Relational Algebra by Way of Adjunctions

Jeremy Gibbons
(joint work with Fritz Henglein, Ralf Hinze, Nicolas Wu)
DBPL, October 2015
1. Summary

- bulk types (sets, bags, lists) are *monads*
- monads have nice *mathematical foundations via adjunctions*
- monads support *comprehensions*
- comprehension syntax provides a *query notation*

\[
\begin{align*}
[ (\text{customer}.\text{name}, \text{invoice}.\text{amount}) \\
| \text{customer} \leftarrow \text{customers}, \\
\text{invoice} \leftarrow \text{invoices}, \\
\text{customer}.\text{cid} = \text{invoice}.\text{customer}, \\
\text{invoice}.\text{due} \leq \text{today} ]
\end{align*}
\]

- monad structure explains *selection, projection*
- less obvious how to explain *join*
2. Galois connections

Relating monotonic functions between two ordered sets:

\[(A, \leq) \perp (B, \subseteq)\]

means \(f b \leq a \iff b \subseteq g a\)

For example,

\[(\mathbb{R}, \leq_{\mathbb{R}}) \perp (\mathbb{Z}, \leq_{\mathbb{Z}})\]

“Change of coordinates” can sometimes simplify reasoning; eg rhs gives \(n \times k \leq m \iff n \leq m \div k\), and multiplication is easier to reason about than rounding division.
3. Category theory from ordered sets

A category $\mathcal{C}$ consists of

- a set* $|\mathcal{C}|$ of objects,
- a set* $\mathcal{C}(X, Y)$ of arrows $X \to Y$ for each $X, Y : |\mathcal{C}|$,
- identity arrows $id_X : X \to X$ for each $X$
- composition $f \cdot g : X \to Z$ of compatible arrows $g : X \to Y$ and $f : Y \to Z$,
- such that composition is associative, with identities as units.

Think of a directed graph, with vertices as objects and paths as arrows.

An ordered set $(A, \leq)$ is a degenerate category, with objects $A$ and a unique arrow $a \to b$ iff $a \leq b$.

\[ \cdots \rightarrow -2 \rightarrow -1 \rightarrow 0 \rightarrow 1 \rightarrow 2 \rightarrow \cdots \]

Many categorical concepts are generalisations from ordered sets.

*proviso…
4. Concrete categories

Ordered sets are a concrete category: roughly,

- the objects are sets with additional structure
- the arrows are structure-preserving mappings

Many useful categories are of this form.

For example, the category $\textbf{CMon}$ has commutative monoids $(M, \otimes, \epsilon)$ as objects, and homomorphisms $h : (M, \otimes, \epsilon) \to (M', \oplus, \epsilon')$ as arrows:

\[
\begin{align*}
h (m \otimes n) &= h m \oplus h n \\
h \epsilon &= \epsilon'
\end{align*}
\]

Trivially, category $\textbf{Set}$ has sets as objects, and total functions as arrows.
5. Functors

Categories are themselves structured objects...

A functor $F : C \rightarrow D$ is an operation on both objects and arrows, preserving the structure: $F f : F X \rightarrow F Y$ when $f : X \rightarrow Y$, and

\[
F \ id_X = id_{F X} \\
F (f \cdot g) = F f \cdot F g
\]

For example, forgetful functor $U : \text{CMon} \rightarrow \text{Set}$:

\[
U (M, \otimes, \epsilon) = M \\
U (h : (M, \otimes, \epsilon) \rightarrow (M', \oplus, \epsilon')) = h : M \rightarrow M'
\]

Conversely, $\text{Free} : \text{Set} \rightarrow \text{CMon}$ generates the free commutative monoid (ie bags) on a set of elements:

\[
\text{Free } A = (\text{Bag } A, \cup, \emptyset) \\
\text{Free } (f : A \rightarrow B) = \text{map } f : \text{Bag } A \rightarrow \text{Bag } B
\]
6. Adjunctions

Adjunctions are the categorical generalisation of Galois connections. Given categories $C, D$, and functors $L : D \to C$ and $R : C \to D$, adjunction

\[ C \perp D \]

means

\[ [-] : C(LX, Y) \cong D(X, RY) : [-] \]

A familiar example is given by currying:

\[ \text{Set} \perp \text{Set} \]

with \( curry : \text{Set}(X \times P, Y) \cong \text{Set}(X, Y^P) : curry^\circ \)

hence definitions and properties of \( apply = \text{uncurry } id_{Y^P} : Y^P \times P \to Y \)
7. Products and coproducts

with

\[ \text{fork} : \text{Set}^2(\Delta A, (B, C)) \simeq \text{Set}(A, B \times C) : \text{fork}^\circ \]
\[ \text{junc}^\circ : \text{Set}(A + B, C) \simeq \text{Set}^2((A, B), \Delta C) : \text{junc} \]

hence

\[ \text{dup} = \text{fork id}_{A,A} : \text{Set}(A, A \times A) \]
\[ (\text{fst}, \text{snd}) = \text{fork}^\circ \text{id}_{B \times C} : \text{Set}^2(\Delta(B, C), (B, C)) \]

give tupling and projection. Dually for sums and injections, and generally for any arity—even zero.
8. Free commutative monoids

Adjunctions often capture embedding/projection pairs:

\[ \text{CMon} \perp \text{Set} \]

with \([-]\) : \text{CMon}(\text{Free } A, (M, \otimes, \epsilon)) \cong \text{Set}(A, U (M, \otimes, \epsilon)) : [-]

Unit and counit:

\[
\begin{align*}
\text{single } A &= [id_{\text{Free } A}] : A \to U (\text{Free } A) \\
\text{reduce } M &= [id_M] : \text{Free } (U M) \to M \quad \text{-- for } M = (M, \otimes, \epsilon)
\end{align*}
\]

whence, for \(h : \text{Free } A \to M\) and \(f : A \to U M = M\),

\[ h = \text{reduce } M \cdot \text{Free } f \iff U h \cdot \text{single } A = f \]

ie 1-to-1 correspondence between homomorphisms from the free commutative monoid (bags) and their behaviour on singletons.
9. Aggregation

Aggregations are bag homomorphisms:

<table>
<thead>
<tr>
<th>aggregation</th>
<th>monoid</th>
<th>action on singletons</th>
</tr>
</thead>
<tbody>
<tr>
<td>count</td>
<td>((\mathbb{N}, 0, +))</td>
<td>({a} \mapsto 1)</td>
</tr>
<tr>
<td>sum</td>
<td>((\mathbb{R}, 0, +))</td>
<td>({a} \mapsto a)</td>
</tr>
<tr>
<td>max</td>
<td>((\mathbb{Z}, \text{minBound}, \text{max}))</td>
<td>({a} \mapsto a)</td>
</tr>
<tr>
<td>min</td>
<td>((\mathbb{Z}, \text{maxBound}, \text{min}))</td>
<td>({a} \mapsto a)</td>
</tr>
<tr>
<td>all</td>
<td>((\mathbb{B}, \text{True}, \land))</td>
<td>({a} \mapsto a)</td>
</tr>
<tr>
<td>any</td>
<td>((\mathbb{B}, \text{False}, \lor))</td>
<td>({a} \mapsto a)</td>
</tr>
</tbody>
</table>

Selection is a homomorphism, to bags, using action

\[
\text{guard} : (A \to \mathbb{B}) \to \text{Bag} A \to \text{Bag} A
\]

\[
\text{guard } p\ a = \text{if } p\ a\ \text{then } \{a\} \text{ else } \emptyset
\]

Laws about selections follow from laws of homomorphisms (and of coproducts, since \(\mathbb{B} = 1 + 1\)).
10. Monads

Bags form a *monad* \((\text{Bag}, \text{union}, \text{single})\) with

\[
\begin{align*}
\text{Bag} & = U \cdot \text{Free} \\
\text{union} & : \text{Bag} (\text{Bag} A) \to \text{Bag} A \\
\text{single} & : A \to \text{Bag} A
\end{align*}
\]

which justifies the use of comprehension notation \(\{ f \ a \ b \mid a \leftarrow x, b \leftarrow g \ a \}\).

In fact, for any adjunction \(L \dashv R\) between \(C\) and \(D\), we get a monad \((T, \mu, \eta)\) on \(D\), where

\[
\begin{align*}
T & = R \cdot L \\
\mu A & = R [id_A] L : T (T A) \to T A \\
\eta A & = [id_A] : A \to T A
\end{align*}
\]
11. Maps

Database indexes are essentially maps $\text{Map } K \ V = V^K$. Maps $(-)^K$ from $K$ form a monad (the Reader monad in Haskell), so arise from an adjunction.

The laws of exponents arise from this adjunction, and from those for products and coproducts:

- $\text{Map } 0 \ V \cong 1$
- $\text{Map } 1 \ V \cong V$
- $\text{Map } (K_1 + K_2) \ V \cong \text{Map } K_1 \ V \times \text{Map } K_2 \ V$
- $\text{Map } (K_1 \times K_2) \ V \cong \text{Map } K_1 \ (\text{Map } K_2 \ V)$
- $\text{Map } K \ 1 \cong 1$
- $\text{Map } K \ (V_1 \times V_2) \cong \text{Map } K \ V_1 \times \text{Map } K \ V_2 : \text{merge}$
12. Indexing

Relations are in 1-to-1 correspondence with set-valued functions:

\[
\begin{array}{c}
\text{Rel} \downarrow J \downarrow \text{Set} \downarrow E \downarrow \text{Set} \\
\end{array}
\]

where \( J \) embeds, and \( E \ R : A \to \text{Set} \ B \) for \( R : A \sim B \).

Moreover, the correspondence remains valid for bags:

\[
\text{index} : \text{Bag} (K \times V) \simeq \text{Map} K (\text{Bag} V)
\]

Together, \textit{index} and \textit{merge} give efficient relational joins:

\[
x f \bowtie g y = \text{flatten} (\text{Map} K \ cp (\text{merge} (\text{groupBy} f x, \text{groupBy} g y)))
\]

\text{groupBy} : (V \to K) \to \text{Bag} V \to \text{Map} K (\text{Bag} V)

\text{flatten} : \text{Map} K (\text{Bag} V) \to \text{Bag} V
13. Pointed sets and finite maps

Model *finite maps* $\text{Map}_*$ not as partial functions, but *total* functions to a *pointed* codomain $(A, a)$, i.e. a set $A$ with a distinguished element $a : A$.

Pointed sets and point-preserving functions form a category $\text{Set}_*$. There is an adjunction to $\text{Set}$, via

$$
\begin{array}{ccc}
\text{Set}_* & \bot & \text{Set} \\
\xleftarrow{\text{Maybe}} & & \xrightarrow{U}
\end{array}
$$

where $\text{Maybe } A \simeq 1 + A$ adds a point, and $U (A, a) = A$ discards it.

In particular, $(\text{Bag } A, \emptyset)$ is a pointed set. Moreover, $\text{Bag } f$ is point-preserving, so we get a functor $\text{Bag}_* : \text{Set} \to \text{Set}_*$.

Indexing remains an isomorphism:

$$
\text{index} : \text{Bag}_* (K \times V) \simeq \text{Map}_* K (\text{Bag}_* V)
$$
14. Graded monads

A catch: finite maps aren’t a monad, because

\[ \eta a = \lambda k \rightarrow a : A \rightarrow \text{Map } K A \]

in general yields an infinite map.

However, finite maps are a \textit{graded monad}*: for monoid \((M, \otimes, \epsilon)\),

\[
\mu X : T_m (T_n X) \rightarrow T_{m \otimes n} X \\
\eta X : X \rightarrow T_\epsilon X
\]

satisfying the usual laws. These too arise from adjunctions*.

We use the monoid \((\mathbb{K}, \times, 1)\) of finite key types under product.
15. Conclusions

- *Monad comprehensions* for database queries
- Structure arising from *adjunctions*
- Equivalences from *universal properties*
- Fitting in *relational joins*, via indexing
- To do: calculating *query optimisations*

Thanks to EPSRC *Unifying Theories of Generic Programming* for funding.
