Abstract

Background: Innate immune signaling pathways in animals and plants are regulated by mitogen-activated protein kinase (MAPK) cascades. MAP kinase 4 (MPK4) functions downstream of innate immune receptors via a nuclear substrate MKS1 to regulate the activity of the WRKY33 transcription factor, which in turn controls the production of anti-microbial phytoalexins.

Methodology/Principal Findings: We investigate the role of MKS1 in basal resistance and the importance of its N- and C-terminal domains for MKS1 function. We used the information that mks1 loss-of-function partially suppresses the mpk4 loss-of-function phenotype, and that transgenic expression of functional MKS1 in mpk4/mks1 double mutants reverted the mpk4 dwarf phenotype. Transformation of mks1/mpk4 with mutant versions of MKS1 constructs showed that a single amino acid substitution in a putative MAP kinase docking domain, MKS1-L32A, or a truncated MKS1 version unable to interact with WRKY33, were deficient in reverting the double mutant to the mpk4 phenotype. These results demonstrate functional requirement in MKS1 for the interaction with MPK4 and WRKY33. In addition, nuclear localization of MKS1 was shown to depend on an intact N-terminal domain. Furthermore, loss-of-function mks1 mutants exhibited increased susceptibility to strains of Pseudomonas syringae and Hya|operonospora arabidopsidis, indicating that MKS1 plays a role in basal defense responses.

Conclusions: Taken together, our results indicate that MKS1 function and subcellular location requires an intact N-terminus important for both MPK4 and WRKY33 interactions.

Introduction

Plants are constantly exposed to a broad range of microbes and have evolved an innate immune system to defend against invading pathogens [1,2]. Part of this system is based on the perception of pathogen- or microbe-associated molecular patterns (PAMPs or MAMPs) through pattern recognition receptors (PRRs) at the cell surface. A common mechanism to transduce such signals into cellular responses is the activation of mitogen-activated protein kinase (MAPK) cascades. These cascades consist of MAPKKK-MAPKK-MAPK modules that link upstream receptors and downstream targets leading to rapid activation of defense responses upon recognition of invading pathogens [3,4].

Loss of Arabidopsis MAP kinase 4 (MPK4) activity leads to dramatic changes in gene-expression, elevated levels of the phytohormone salicylic-acid (SA), increased resistance to biotrophic pathogens, and mpk4 loss-of-function mutants are extreme dwarfs [5]. The resistance-associated phenotypes of mpk4 are suppressed by mutations in two defense regulators, ENHANCED DISEASE SUSCEPTIBILITY 1 (EDS1) and PHYTOALEXIN DEFICIENT 4 (PAD4) [6]. In contrast, MPK4 seems to be required for the expression of defense genes that rely on the phytohormones ethylene and jasmonate (ET/JA) and efficient resistance against necrotrophic pathogens. Interestingly, EDS1 was found to be responsible for blocking PDF1.2 expression in mpk4 single mutants, because mpk4/eds1 double homozygotes express PDF1.2 in response to jasmonate [6].

MAP kinase substrate 1 (MKS1) was previously identified as a MPK4 substrate, and analysis of transgenic plants, and transcript profiling indicated that MKS1 was required for full resistance in mpk4 mutants [7]. MKS1 was also found to interact in vivo with the transcription factor WRKY33, and may function as an adaptor linking MPK4 activity to WRKY-regulated gene expression [8]. WRKY transcription factors constitute a family of defense-related factors that bind W-box sequences in the promoters of pathogen-induced genes, including WRKY genes themselves [9,10]. It was
shown that MPK4 and MKS1 associate in a complex with WRKY33, and that activation of MPK4 and phosphorylation of MKS1 upon infection leads to release of MKS1 and WRKY33 from MPK4. Consequently, WRKY33 targeted the promoter of *PHYTOALEXIN-DEFICIENT3* (*PAD3*), encoding a cytochrome P450 monooxygenase required for the production of the antimicrobial phytoalexin camalexin [8].

MKS1 contains a plant-specific VQ motif that is found in about 35 predicted *Arabidopsis* proteins [11]. These proteins are generally small and share little significant similarity to other sequenced or predicted proteins. Other than the regions containing the conserved VQ motif, their primary structures also appear to be highly diverse [11].

MAP kinases phosphorylate their substrates on conserved Ser/Thr-Pro phosphoacceptor sites [12]. However, targeting of a MAP kinase to a specific substrate does not only depend on the phosphoacceptor site, but is also mediated by physical interaction between the kinase and MAP kinase docking domains present on substrate protein [13]. Docking domains have been identified in numerous MAP kinase substrates, and consist of a K/R1-4-X1-6-Tyr-Pro phosphoacceptor module, where φ3 and φ4 are hydrophobic residues (leucine, isoleucine or valine) [13].

MKS1 contains 12 Ser-Pro and our initial analyses indicated that MPK4 phosphorylated MKS1 in *Arabidopsis* cells, and perhaps on other Ser-Pro sites throughout MKS1 [7]. In a more recent paper we did not detect phosphorylation of Ser30, but only activated MPK4 phosphorylation of MKS1. However, using this technique we did not detect phosphorylation of Ser30, but only phosphorylation of Ser2, Ser108, and Ser120 [14].

Here we show that MKS1 plays a pivotal role in basal defense responses in *Arabidopsis* as loss-of-function mks1 mutants exhibit increased susceptibility to strains of *Pseudomonas syringae* and *Hyaloperonospora arabidopsidis*. In addition, we show that MKS1 function and subcellular location requires an intact N-terminus important for both MPK4 and WRKY33 interactions.

**Results**

**mks1 suppresses the mpk4 dwarfism phenotype**

We previously demonstrated that reduced accumulation of *MKS1* mRNA via RNAi (*MKS1*-RNAi) partially suppressed the dwarfism and disease resistance conferred by *mpk4* mutation in homozygous *mpk4* expressing *MKS1*-RNAi [7]. However, the resistance phenotype of *MKS1*-RNAi was not significantly different from wild-type [7]. This may have been because MKS1 does not contribute to basal defense, or that the levels of *MKS1* mRNA in *MKS1*-RNAi plants were sufficient to mask such a phenotype. To distinguish between these two possibilities, we obtained an *MKS1* Ds-insertion line (GT108403). RT-PCR identified *MKS1* transcripts in the parental wild-type background *Ler* but not in the *mks1* insertion mutants (Figure 1A). Furthermore, immuno-blotting with an MKS1-specific antibody [7] demonstrated the presence of MKS1 protein in *Ler* and in transgenic plants in which *MKS1* expression is controlled by the *CmMY 35S* promoter, but failed to detect MKS1 protein in the *mks1* insertion line (Figure 1B). The *mks1* null mutant was expected to suppress the *mpk4* phenotype at least to the same level as seen with *MKS1*-RNAi [7]. Therefore, the *mks1* insertion allele was crossed into the *mpk4* background and double mutant *mpk4/mks1* progeny confirmed by PCR (data not shown). Notably, the suppression of *mpk4* dwarfism and leaf epinasty by the *mks1* insertion allele was stronger than what we originally found with *MKS1*-RNAi (Figure 1C).

**mks1 mutants exhibit decreased basal resistance to pathogens**

Since the *mks1* mutant is a stronger suppressor of *mpk4* than *MKS1*-RNAi, MKS1 could be engaged in cellular processes, including general plant defense responses, not detected via the RNAi approach. We therefore monitored the disease susceptibility of *mks1* infected with *P. syringae* strain DC3000. Time-course replicate assays revealed that, 2 and 4 days after inoculation with virulent *P. syringae* strain DC3000, bacterial growth in leaves of soil grown *mks1* mutant plants was up to 10-fold higher compared to *Ler* wild-type (Figure 2A). To verify this finding, we extended the analysis with another pathogen class by inoculating *mks1* mutants with a virulent isolate (Cala 2) of the oomycete *Hyaloperonospora arabidopsidis*. Colonization by the virulent Cala 2 isolate was considerably more pronounced in *mks1* compared to *Ler*, as revealed by the number of spores per plant (Figure 2B) and by macroscopic disease symptoms (data not shown). This suggests that loss of MKS1 affects induced defense responses. We therefore examined the accumulation of the pathogenesis-related marker *PR1* mRNA by real-time RT-PCR in *mks1* mutants after challenge with virulent *P. syringae*. However, *PR1* accumulated to much lower levels in *mks1* compared to wild-type *Ler* leaves 2 days after infection (Figure 2C). These results indicate that MKS1 plays a role in maintaining basal resistance.

**Overexpression of MKS1 leads to susceptibility to the necrotrophic pathogen *B. cinerea***

To further characterize the role of MKS1 in disease resistance, we included a necrotrophic pathogen in our analysis and inoculated both *mks1* mutants and transgenic plants overexpressing *MKS1* (*35S:MKS1*) with the fungus *B. cinerea*. The *35S:MKS1* plants displayed severe tissue damage 5 days after inoculation (DAI) compared to both *mks1* and the *Ler* wild-type (Figure 3A). The size of disease lesions on inoculated leaves of *35S:MKS1* was increased compared to *Ler* wild-type (Figure 3B) and *mks1* (data not shown). Moreover, fewer spreading lesions appeared in *mks1* plants than in
35S:MKS1 or Ler wild-type after inoculation (data not shown). To determine whether enhanced susceptibility to \textit{B. cinerea} in 35S:MKS1 is associated with altered defense responses against necrotrophs, we determined the expression of the defense marker gene \textit{PDF1.2} following \textit{B. cinerea} inoculation. The expression of \textit{PDF1.2} was significantly reduced in 35S:MKS1 compared with wild-type, whereas \textit{PDF1.2} was highly elevated in \textit{mks1} (Figure 3C). Collectively, these data indicate that MKS1 negatively regulate resistance responses required to combat the necrotrophic pathogen \textit{B. cinerea}.

**MPK4 and WRKY33 interact with different regions of MKS1**

We previously showed that MKS1 interacts \textit{in vivo} with MPK4 and WRKY33 [7,8]. To further specify which domains of MKS1 are important for these interactions, we performed a directed yeast two-hybrid analysis with two N-terminal deletions and three C-terminal deletions (Figure 4). N-terminal deletion 1, MKS1\textsubscript{DN1}, lacks domain 1 containing a putative MAP kinase docking domain [13]. MKS1\textsubscript{DN2}, lacks both domain 1 and domain 2 (containing a conserved VQ motif) [7]. MKS1\textsubscript{DC3}, contains only domain 1 and part of domain 2. MKS1\textsubscript{DC2} consist of both domains, while MKS1\textsubscript{DC1} only lacks the 27 most C-terminal amino acids of MKS1. Table 1 summarizes the results of the yeast two-hybrid screen. Unfortunately, the MKS1\textsubscript{DN2} truncation was self-activating and was therefore omitted from further analysis. Nevertheless, we found that MPK4 interacted with all C-terminal truncations, but not with MKS1\textsubscript{DN1}, indicating that domain 1 of MKS1, containing the putative MAP kinase docking domain, is necessary for interaction of MPK4 with MKS1 (Figure 4).

doi:10.1371/journal.pone.0014364.g003
WRKY33 interacted with MKS1ΔN1, MKS1ΔC1 and MKS1ΔC2, but not with the shortest version of MKS1, MKS1ΔC3, suggesting that WRKY33 interacts with the region of 74 to 128 residues of MKS1 that includes domain 2 with the VQ motif (Figure 4).

MPK4 only interacts with an intact N-terminal domain of MKS1

To investigate the importance of the protein sequence in the putative MAP kinase docking domain of MKS1, we made 18 alanine substitutions (Figure 5A) and conducted a directed yeast two-hybrid assay with MPK4 as bait. The amino acids to be substituted were selected by their level of conservation among different plant MKS1 homologs (Figure S1). Of the 18 alanine substitutions, six were found to be important for interaction (Figure 5B). Two possible $\phi_\alpha$-$x$-$\phi_\beta$ motifs exist in the N-terminus of MKS1: Leu22-Gln23-Ile24 and Leu32-Ser33-Val34 (Figure 5A). The $\phi_\alpha$-$x$-$\phi_\beta$ motif inserts into the docking groove on the MAP kinase, and alanine substitutions in this motif have been shown to block activation of the MAP2A transcription factor by the MAPK p38 in mammalian cells [15]. Since substituting Leu32 with alanine caused disruption of binding and no such effect is observed for substitutions of Leu22, Gln23 or Ile24, it is likely that Leu32-Ser33-Val34 constitutes the relevant $\phi_\alpha$-$x$-$\phi_\beta$ motif. This is also supported by the observation that Leu32 and Val34 are highly conserved among the different MKS1 homologs, whereas Leu22 shows no conservation at all (Figure S1). This points to the existence of a docking domain at the N-terminus of MKS1 fitting the $K/R_{1-4}$-$X_{1-6}$-$\phi_\alpha$-$x$-$\phi_\beta$ module [16]. However, we previously showed that MPK4 phosphorylates MKS1 in vitro on Ser30 [7], and mammalian studies have shown that the classical docking motif binds to a region that lies on the other side of the protein to a phosphorylation site [17]. These results would exclude a classical docking domain within a phosphorylation site. However, a recent study shows that in planta activation of MPK4 by inoculation with P. syringae DC3000 expressing the AvrRpm1 avirulence factor only phosphorylates MKS1 on Ser72, Ser108, and Ser120, and not on Ser30 [14]. If this is the case, it is probable the N-terminus of MKS1 contains a ‘classical’ docking domain.

An intact N-terminus is required for MKS1 nuclear localization

MKS1 is exclusive localized in nuclei and MPK4 primarily localizes to the nucleus, consistent with their ability to interact in vivo [7]. To examine the subcellular localization of the different mutant versions of MKS1, we analyzed the localization of the MKS1-L32A point mutation and the five different truncations of MKS1 by gene fusions to green fluorescent protein (GFP). To confirm that intact GFP-MKS1 fusion proteins were produced, immuno-blots were performed using anti-GFP antibody (Figure S2). Full length MKS1 produces strong GFP fluorescence in the nucleus (Figure 6, MKS1). The C-terminal truncations MKS1ΔC1 and MKS1ΔC2 also localized almost exclusively in nuclei (Figure 6, ΔC1 and ΔC2), whereas MKS1ΔC3 and the two N-terminal truncations, MKS1ΔN1 and MKS1ΔN2, displayed weak fluorescence in both nuclei and cytoplasm (Figure 6, ΔC3, ΔN1 and ΔN2). Interestingly, MKS1-L32A only seemed to display weak fluorescence in the nucleus and was primarily localized to the cytosolic compartment (Figure 6, L32A). These results indicate that the region of MKS1 including residues 129-223 are dispensable for its specific nuclear localization. On the other hand, residues 1-74 (MKS1ΔC3), C1 or C2 truncations of MKS1 revert the dwarf phenotype. These results indicate

An intact N-terminus is required for MKS1 function

To examine the biological significance of the MKS1-L32A point mutation and the five different truncations of MKS1, we transformed these six constructs into mpk4/mks1 double mutant to assess their ability to complement mpk4/mks1 phenotype. As noted in Figure 1C, mks1 partially suppressed the mpk4 phenotype, and re-introducing functional MKS1 reverted mpk4/mks1 to the mpk4 dwarf phenotype. As can be seen in Figure 7A, only MKS1ΔC1 or MKS1ΔC2 truncations of MKS1 reverted the mpk4/mks1 phenotype to the mpk4 dwarf phenotype. These results indicate
that a functional MKS1 protein requires an intact N-terminus important for both MPK4 and WRKY33 interactions. To confirm that intact proteins were produced in these experiments, immunoblots were performed using anti-MKS1 (Figure S3). However, MKS1D is truncated within the N-terminal sequence against which the anti-MKS1 antibody was raised and are therefore not recognized. MKS1D was also not recognized by the anti-MKS1 antibody, although this truncation includes the sequence used to raise the anti-MKS1 antibody. An explanation may be that MKS1D is not folded correctly and therefore not recognized by the antibody, because MKS1D expressed in E. coli was also not recognized although the mRNA was detected by RT-PCR (data not shown).

Because overexpression of MKS1 leads to increased expression of PRI [7], we examined whether ectopic expression of the point mutation construct MKS1-L32A or the truncations of MKS1 would have any effect on PRI expression (Figure 7B). Only transgenic plants overexpressing the C-terminal truncations MKS1D and MKS1D exhibited high PRI expression, with levels comparable to those in mpk4 or 35S:MKS1, whereas MKS1D, MKS1DN1, MKS1DN2 and MKS1-D3 showed similar PRI expression levels as mpk4/mks1 or Ler wild-type (Figure 7B). To confirm that PRI expression does not correlate with transgenic MKS1oe levels, we next analyzed the expression levels of the different transgenic MKS1oe versions. This showed that PRI mRNAs levels are independent of the mRNA levels produced by the transgenic MKS1oe constructs, indicating that the increased PRI mRNAs do not simply reflect the levels of the transgenic MKS1oe mRNAs (Figure 7C).

Discussion

We show that a loss-of-function mks1 insertion allele is a much stronger suppressor of mpk4 than MKS1-RNAi. In addition, we found that this mks1 mutant exhibits decreased basal resistance to biotrophic pathogens, an effect not seen in plants with reduced accumulation of MKS1 mRNA via RNAi. These observations are important because they demonstrate that MKS1 plays a role in maintaining basal resistance at levels similar to that found for other resistance signaling proteins like EDS1 and PAD4 [18]. That MKS1 plays important roles in plant resistance responses is further supported by the recent finding that the snc4-1D mutant, which exhibits increased resistance responses, is partially suppressed by mks1 [19].

MKS1 interacts with both MPK4 and WRKY33. Using directed yeast two-hybrid screens with different MKS1 deletion forms, we found that MKS1 plays a role in maintaining basal resistance at levels similar to that found for other resistance signaling proteins like EDS1 and PAD4 [18]. That MKS1 plays important roles in plant resistance responses is further supported by the recent finding that the snc4-1D mutant, which exhibits increased resistance responses, is partially suppressed by mks1 [19].

MKS1 interacts with both MPK4 and WRKY33. Using directed yeast two-hybrid screens with different MKS1 deletion forms, we found that the N-terminal domain, which contains a putative kinase docking domain, interacts with MPK4, whereas WRKY33 was found to interact with a plant-specific VQ motif-containing domain. MKS1 is a member of a small protein family sharing this conserved VQ motif of unknown function, but other than this region their primary structures are highly diverse. Two other VQ motif-containing proteins have been characterized: SIB1 is a nuclear-encoded protein that is targeted to chloroplasts and interacts specifically with plastid RNA polymerase σ-factor Sig1 [20], and AtCaMBP25 is a calmodulin-binding protein involved in abiotic stress tolerance [21]. Interestingly, SIB1 was also found to be induced by SA [22], and to be involved in disease resistance [11]. Thus, the sib1 loss-of-function mutation is
compromised in the induction of some defense-related genes triggered by pathogen infection, whereas over-expression of SIB1 activates defense-related gene expression following pathogen infection, leading to enhanced resistance to infection by P. syringae. It is thus tempting to speculate that like MKS1 and SIB1, other VQ domain-containing proteins also play roles in basal resistance. Future studies, including double mutant analysis and protein interaction experiments, will clarify the role this protein family may exert in plant immunity and whether MKS1 and SIB1 play similar roles in the MPK4 regulatory node.

We previously showed that MKS1 is localized in nuclei and interacts with MPK4 in this compartment [7,8]. The in-depth analysis of MKS1 constructs presented here demonstrates that the N-terminal part of MKS1 is important for MPK4 interaction. In addition, a single amino acid change, L32A, within the putative MAPK docking motif of MKS1, is sufficient to reduce MKS1 and MPK4 interaction and to exclude MKS1 from nuclei. In addition, expression of MKS1 L32A fails to revert the phenotype of the mpk4/mks1 double mutant. Therefore, Leu32 of MKS1 appears to be essential for all known aspects of MKS1 function, indicating that the integrity of the MKS1 N-terminal is essential for proper function.

An intact N-terminus including a putative MAPK docking domain and a VQ motif seems to be required for MKS1 to revert mks1/mpk4 to the mpk4 dwarf phenotype as visualized by the phenotypic inspection of mks1/mpk4 plants expressing MKS1-L32A, MKS1ΔN1, MKS1ΔN2 and MKS1ΔC3. In contrast, amino acids 127-223 comprising the C-terminus are dispensable for this effect. These results solidify the importance of the N-terminal region for MKS1 function. As noted above, domain 2 contains a VQ motif and is required for interaction with WRKY33, suggesting that WRKY33 is involved in the mpk4 dwarf phenotype. As observed in the reversion effects for mks1/mpk4, correct MKS1 nuclear localization also depends on an intact docking domain, as evidenced by the increased cytoplasmic localization of MKS1-L32A, MKS1ΔN1, MKS1ΔN2 and MKS1ΔC3.

Materials and Methods

Plant Materials and Growth Conditions

mpk4 [5], mks1 [GT.108403; [8]] and the mpk4/mks1 double mutant, all in Landsberg (Ler) background, were grown in chambers under short-day (8 h light/16 h darkness). Day and night temperatures were 21 and 16°C, respectively.
Genotyping

The following gene-specific primers were used for PCR-based genotyping for \textit{mpk4}: \text{MPK4fwd}: 5'-CAGAGATGCTGATGAT-TAGTAACA-3' and \text{MPK4rev}: 5'-GGATCCATGTCGGCG-GAGAGTTGTTTC-3' and for \textit{mks1}: \text{MKS1fwd}: 5'-ATCTGGCGGCGGTGGAGATGT-3' and \text{MKS1rev-3'UTR}: 5'-GCTACTACATTTGATATGTC-3'. \text{DS1}: 5'-GTTTTCTGT-TTCCGTCCCCGAAG-3' recognizes the Ds transposon insertion in \textit{mpk4} and \textit{mks1}. For genotyping the \textit{MKS1} truncations and the \textit{MKS1-L32A} point mutation, the following primers were used: \text{MKS1fwd}: 5'-ATCTGGCGGCGGTGGAGATGT-3' and \text{MKS1rev-3'NOS}: 5'-CGGCAACAGGATCTTCTTT-3'. For

CACAGAACCGAGAAG-3’ and MKS1rev-3’NOS 5’TGGC-
AACAGATTGACTTCT-3’ were used.

Bacterial Growth Assays

Five-week-old plants were infiltrated with *Pseudomonas syringae* tomato DC3000 and growth assays performed according to [23]. Infections with *Hyaloperonospora arabidopsidis* were performed using 105 conidia/mL under conditions described previously [24].

Plasmid Construction and *Arabidopsis* Transformation

For yeast two-hybrids, the five truncated versions of *MKS1, MPK4* and *WRKY33* cDNA were amplified by RT-PCR from wild-type Ler using the primers listed in Table S1. Hereafter, the truncated versions of *MKS1* were cloned into the *Not*I and *EcoRI* sites of pGBKTT7 and MPK4, WRKY25 and WRKY33 cDNA were cloned into the *Not*I and *EcoRI* sites of pGADT7.

For transgenic analyses, the five truncations of MKS1 and the MKS1-L32A point mutant were cloned into the *Not*I site of the binary vector pJL12 using primers listed in Table S2. The pJL12 vector was derived from the binary vector pCB302-3 [25]. pCB302-3 contains two *Not*I sites, one in MCS2 and another in the vector backbone. In pJL12, the *Not*I site in the vector backbone has been deleted by a silent mutation. The six different pJL12-MKS1 vectors were transformed into *Agrobacterium* silent mutation. The six different pJL12-MKS1 vectors were transgene were identified with BASTA.

MKS1 (HYB 330-01; Statens Serum Institut, Denmark). HRP conjugated monoclonal anti-Mouse IgG from DakoCytomation. HRP conjugated antibody was visualized using the Supersignal West Pico kit (Pierce).

RNA Preparation and Quantitative RT-PCR

RNA was isolated from 3-week old plants grown under short day conditions using the RiboPure kit (Ambion) according to the manufacturer’s instructions. Quantitative RT-PCR was performed as described previously [8].

Confocal Microscopy

Analysis of GFP expression in mesophyll cells of young leaves was performed by confocal laser-scanning microscopy on a Zeiss LSM 510 confocal microscope equipped for epifluorescence analysis of GFP fluorescence.

At: Arabidopsis thaliana; Pt: Populus trichocarpa; Rc: Ricinus communis; Vc: Vitis vinifera; Zm: Zea mays; Sb: Sorghum bicolor; Os: Oryza sativa. Found at: doi:10.1371/journal.pone.0014364.s001 (0.37 MB TIF)

**Figure S2** Immuno-blot of total cellular proteins from transgenic plants expressing MKS1-GFP fusion constructs immunodetected with anti-GFP antibody. Truncation MKS1 ΔN2 is so highly expressed that a small fraction of the correct fusion is degraded into smaller fragments. Found at: doi:10.1371/journal.pone.0014364.s002 (0.38 MB TIF)

**Figure S3** Immuno-blot of total cellular proteins from transgenic mpk4/mks1 plants expressing MKS1 truncations immunodetected with anti-MKS1 antibody. Several lines for each construct were tested and only lines with the expected protein size were used for further analyses. Truncations MKS1ΔN1, MKS1ΔN2 and MKS1ΔC3 are not recognized by the anti-MKS1 antibody. Found at: doi:10.1371/journal.pone.0014364.s003 (1.08 MB TIF)

**Table S1** List of primers used for yeast two-hybrid assays. Found at: doi:10.1371/journal.pone.0014364.s004 (0.22 MB TIF)

**Table S2** List of primers used for complementation studies. Found at: doi:10.1371/journal.pone.0014364.s005 (0.23 MB TIF)

**Table S3** List of primers used for GFP fusion constructs. Found at: doi:10.1371/journal.pone.0014364.s006 (0.22 MB TIF)

Acknowledgments

We thank Sukawad Vongvitsitkun for technical assistance and Stephan Thorgrimsen for assistance with the immuno-blots.

Author Contributions

Conceived and designed the experiments: KP JLQ JM. Performed the experiments: KP JLQ JLJ BKF SH. Analyzed the data: KP JLQ JLJ BKF MP. Contributed reagents/materials/analysis tools: JLQ MP. Wrote the paper: KP JM MP.
