First Passage Times of General Sequences of Random Vectors: 
A Large Deviations Approach

Abstract

Suppose \( Y_1, Y_2, \ldots \in \mathbb{R}^d \) is a sequence of random variables such that the probability law of \( Y_n/n \) satisfies the large deviation principle and suppose \( A \subseteq \mathbb{R}^d \). Let \( T(A) = \inf \{ n : Y_n \in A \} \) be the first passage time and, to obtain a suitable scaling, let \( T^\epsilon(A) = \epsilon \cdot \inf \{ n : Y_n \in A/\epsilon \} \). We consider the asymptotic behavior of \( T^\epsilon(A) \) as \( \epsilon \to 0 \). We show that the the probability law of \( T^\epsilon(A) \) satisfies the large deviation principle; in particular, \( \mathbb{P} \{ T^\epsilon(A) \in C \} \approx \exp \{ - \inf_{\tau \in C} I_A(\tau)/\epsilon \} \) as \( \epsilon \to 0 \), where \( I_A(\cdot) \) is a large deviation rate function and \( C \) is any open or closed subset of \([0, \infty)\). We then establish conditional laws of large numbers for the normalized first passage time \( T^\epsilon(A) \) and normalized first passage place \( Y^\epsilon_{T^\epsilon(A)} \).

1 Introduction

Let \( Y_1, Y_2, \ldots \) be a sequence of random variables taking values in \( \mathbb{R}^d \). For any subset \( A \subseteq \mathbb{R}^d \), let \( T(A) = \inf \{ n : Y_n \in A \} \) be the first passage time, i.e., the first time that the sequence \( Y_1, Y_2, \ldots \) hits the set \( A \). The purpose of this article is to study the distributional properties of \( T(A) \) and, in effect, to determine the limiting behavior of \( T(A) \) as the set \( A \) drifts to infinity, or, more precisely, the limiting behavior of

\[
T^\epsilon(A) = \epsilon \cdot \inf \{ n : Y^\epsilon_n \in A \} \quad \text{as} \quad \epsilon \to 0, \quad \text{where} \quad Y^\epsilon_n = \epsilon Y_n.
\]

Problems of this general type were first studied in the context of collective risk theory by Lundberg (1909). Letting \( Y_t = ct - X_t \), where \( \{X_t\}_{t \geq 0} \) is a compound Poisson process and \( c \) is a positive constant, he considered \( \mathbb{P} \{ Y_t < -1/\epsilon, \text{ some } t \} \), namely the probability that the process \( \{Y_t\}_{t \geq 0} \) ever hits the negative halfline \( (-\infty, -1/\epsilon) \). This is equivalent to \( \mathbb{P} \{ T^\epsilon(A) < \infty \} \), where \( A = (-\infty, -1) \). A well-known result due to Cramér states that if \( \{Y_t\}_{t \geq 0} \) has positive drift, then for certain constants \( C \) and \( R \),

\[
\mathbb{P} \{ T^\epsilon(A) < \infty \} \sim Ce^{-R/\epsilon} \quad \text{as} \quad \epsilon \to 0, \quad (1.1)
\]
where $R$ is identified as the nonzero element of the two-point set $\{\alpha : \Lambda(\alpha) = 0\}$ and $\Lambda$ is the logarithmic moment generating function; see Cramér (1954).

Extensions of Cramér’s estimate have been widely studied, particularly in the setting of random variables taking values in $\mathbb{R}^1$. An extension to the $d$-dimensional setting has been given in Collamore (1996a), where it is shown under certain regularity conditions that if $A$ is any open subset of $\mathbb{R}^d$, then

$$
\lim_{\epsilon \to 0} \epsilon \log P\{T^\epsilon(A) < \infty\} = - \inf_{x \in A} \tilde{I}(x),
$$

(1.2)

where $\tilde{I}$ is the support function of the $d$-dimensional surface $\{\alpha : \Lambda(\alpha) \leq 0\}$. This limiting result is shown to hold, moreover, for general sequences $\{Y_n\}_{n \in \mathbb{Z}^+}$, provided that the probability law of $Y_n/n$ satisfies the large deviation principle. [Various one-dimensional results for general sequences have been established by other authors; see Grandell (1991), Nyrhinen (1994) and references therein.]

While the above results describe $P\{T^\epsilon(A) < \infty\}$ as $\epsilon \to 0$, they give little insight into the actual distribution of $T^\epsilon(A)$. In fact, it is quite easy to construct examples of sequences having the same exponential decay rates in (1.1), but for which the actual distributions of $T^\epsilon(A)$ are very different. It is of interest to develop refinements of (1.1) and (1.2) which yield an improved characterization of $T^\epsilon(A)$.

In the setting of (1.1), such refinements have been given by von Bahr (1974) and Siegmund (1975). They have shown that if $Y = ct - X_t$, where $\{X_t\}_{t \geq 0}$ is a compound Poisson process, or if $\{Y_t\}_{t \geq 0}$ is a more general process, and if $A$ is the halfline $(-\infty, -1)$, then

$$
P\{T^\epsilon(A) \leq \tau(\epsilon)\} \sim Ce^{-R/\epsilon \Phi(y)} \text{ as } \epsilon \to 0,
$$

(1.3)

where $\Phi(\cdot)$ denotes the standard Normal distribution function, $\tau(\epsilon) = \beta_1 + \beta_2 y \sqrt{\epsilon}$, and $C$, $R$, $\beta_1$ and $\beta_2$ are constants. Eq. (1.3) gives the same asymptotic decay for $P\{T^\epsilon(A) < \infty\}$ as was given in (1.1), but it also shows that, conditioned on $\{T^\epsilon(A) < \infty\}$, a proper rescaling of $T^\epsilon(A)$ converges to a Normal distribution. We note that other relevant one-dimensional theorems have been developed by Segerdahl (1955); Martin-Löf (1986), who has established large deviation results e.g. for $P\{T^\epsilon(A) \leq \tau_0\}$ as $\epsilon \to 0$; and very recently by Nyrhinen (1998), who, under a technical condition on the lower bound, has established more complete large deviation results for general sequences $Y_1, Y_2, \ldots \in \mathbb{R}^1$.

Our interest is in developing related limit theorems, but from a viewpoint more general than has been considered in the works of von Bahr, Siegmund, Martin-Löf and Nyrhinen. We are particularly interested in developing such theorems in the setting of the basic large deviations results given, for example, in Varadhan (1984), Ney and Nummelin (1987a,b) and Ellis (1984). Specifically, our objective is to study the case where $A$ is a general subset of $\mathbb{R}^d$ and $Y_1, Y_2, \ldots$ a general sequence of random variables for which the probability law of $Y_n/n$ satisfies the large deviation principle.

Under certain regularity conditions on $\{Y_n\}_{n \in \mathbb{Z}^+} \subset \mathbb{R}^d$ and $A \subset \mathbb{R}^d$, we show

$$
\lim_{\epsilon \to 0} \sup_{F} \epsilon \log P\{T^\epsilon(A) \in F\} \leq - \inf_{\tau \in F} I_A(\tau),
$$

(1.4)

for all sets $F$ which are closed in $[0, \infty)$.
\[
\liminf_{\epsilon \to 0} \epsilon \log P\{T^\epsilon(A) \in G\} \geq -\inf_{\tau \in G} I_A(\tau),
\]
for all sets \(G\) which are open in \([0, \infty)\). \hfill (1.5)

Thus, the probability law of \(T^\epsilon(A)\) satisfies the large deviation principle with rate function \(I_A(\cdot)\). We show that (1.4) and (1.5) hold quite generally, namely, when \(A\) is any subset of \(\mathbb{R}^d\) and when \(Y_1, Y_2, \ldots\) are the sums of an i.i.d. sequence of random variables, or the additive functions of a Markov chain, or a sequence satisfying the conditions of the Gärtner-Ellis theorem. The proofs of (1.4) and (1.5) will rely on large deviations estimates, as \(\epsilon \to 0\), for joint probabilities of the form

\[
P\{(Y_m^\epsilon, Y_n^\epsilon) \in \mathcal{A}, \text{ some } (m, n) \in \mathcal{C}/\epsilon\},
\]
where \(\mathcal{A} \subset \mathbb{R}^{2d}\), \(\mathcal{C} \subset \{((\tau_u, \tau_v) : \tau_v \geq \tau_u \geq 0\},\text{ and }\{Y_n\}_{n \in \mathbb{Z}_+}\) is a general sequence for which the probability law of \(Y_n/n\) satisfies the large deviation principle. See Theorem 4.2 below.

If \(A \subset \mathbb{R}^d\) is convex, then the form of the function \(I_A(\cdot)\) in (1.4) and (1.5) suggests that there should be a most likely normalized first passage time, in the sense that we should have \(T^\epsilon(A) \approx \rho\) for some positive constant \(\rho\). To this end, we show

\[
\lim_{\epsilon \to 0} P\{|T^\epsilon(A) - \rho| > \gamma |T^\epsilon(A) < \infty\} = 0, \text{ for all } \gamma > 0,
\]
for a certain constant \(\rho > 0\). We also establish an analogous result for the normalized first passage place, \(Y_T^\epsilon(A)\), namely,

\[
\lim_{\epsilon \to 0} P\{\|Y_T^\epsilon(A) - x_0\| > \gamma |Y_T^\epsilon(A) < \infty\} = 0, \text{ for all } \gamma > 0,
\]
for a certain point \(x_0\) which lies on the boundary of \(A\). Hence, conditioned on the event \(\{T^\epsilon(A) < \infty\}\), \(T^\epsilon(A)\) converges in probability to \(\rho\) and \(Y_T^\epsilon(A)\) converges in probability to \(x_0\).

We note that large deviations theorems having a similar form to (1.6) and (1.7) have been developed in various other settings. For example, the exit from a domain of a perturbed dynamical system near a point of stable equilibrium has been studied by Freidlin and Wentzell (1984), who have shown under certain circumstances that there is a most likely exit point. Also, certain large exceedance results have been established for Lévy processes \(\subset \mathbb{R}^d\) by Dembo, Karlin and Zeitouni (1994). These last results have recently been extended beyond the i.i.d. or Lévy setting by Zajic (1995).

## 2 Statement of Results

Let \(Y_1, Y_2, \ldots\) be a sequence of random variables taking values in \(\mathbb{R}^d\). Let \(Y_n^\epsilon = \epsilon Y_n\) for all \(\epsilon > 0\) and all \(n \in \mathbb{Z}_+\).

Our objective is to study

\[
T^\epsilon(A) = \epsilon \cdot \inf\{n : Y_n^\epsilon \in A\}
\]
for general sets \(A \subset \mathbb{R}^d\) and, particularly, to determine the limiting behavior of \(T^\epsilon(A)\) as \(\epsilon \to 0\).
First we introduce some further notation. Let

\[ \Lambda(\alpha) = \lim_{n \to \infty} n^{-1} \log \mathbb{E} \exp \{ \langle \alpha, Y_n \rangle \}, \text{ for all } \alpha \in \mathbb{R}^d; \]

\[ Z_{m,n} = (Y_m, Y_n - Y_m), \quad Z^\epsilon_{m,n} = \epsilon Z_{m,n}, \text{ for all } n \geq m; \]

\[ \Lambda_{m,n}(\alpha) = \log \mathbb{E} \exp \{ \langle \alpha, Z_{m,n} \rangle \}, \text{ for all } \alpha \in \mathbb{R}^d \text{ and } n \geq m; \]

\[ \Lambda_{\epsilon}(\alpha) = \lim_{m \to \infty, n \to \infty} n^{-1} \log \mathbb{E} \exp \{ \langle \alpha, Z_{m,n} \rangle \}, \text{ for all } \alpha \in \mathbb{R}^d; \]

\[ \mathcal{L}_{a} f = \{ x : f(x) \leq a \}, \text{ for any } f : \mathbb{R}^d \to \mathbb{R}; \]

\[ \text{cone } S = \{ \lambda x : \lambda \geq 0, x \in S \}; \]

and

\[ \mathcal{B}_{\delta} = \{ x : \inf_{y \in \mathcal{L}_{a} \Lambda^*} \| x - y \| < \delta \}. \]

[It is assumed that the limits in the definitions of \( \Lambda \) and \( \Lambda_{\epsilon} \) exist.] For any set \( S \), let \( \text{ri } S \), \( \partial S \) denote the relative interior, relative boundary of \( S \), respectively; and for any function \( f \), let \( f^* \), \( \text{dom } f \), \( \text{cl } f \), \( 0^* f \) denote the convex conjugate of \( f \), the domain of \( f \), the closure of \( f \), and the recession function of \( f \), respectively. [For definitions, see Rockafellar (1970).]

The following regularity conditions will be imposed on the sequence \( \{ Y_n \}_{n \in \mathbb{Z}^+} \) and the set \( A \).

**Hypotheses: (H0)** The probability law of \( Y_n/n \) satisfies the large deviation principle with a rate function \( I = \Lambda^* \), where \( \Lambda \) is differentiable at every point in its domain.

(H1) For each \( \epsilon \in [0, 1] \) and \( \alpha_u, \alpha_v \in \mathbb{R}^d \), \( \Lambda_{\epsilon}(\alpha_u, \alpha_v) = \epsilon \Lambda(\alpha_u) + (1 - \epsilon) \Lambda(\alpha_v) \).

(H2) For some \( \delta > 0 \), \( \text{cl } A \cap \text{cone } \mathcal{B}_{\delta} = \emptyset \).

To consider the nature of these hypotheses in the context of some standard examples of sequences \( \{ Y_n \}_{n \in \mathbb{Z}^+} \) satisfying the large deviation principle, suppose for example that

\[ Y_n = X_1 + \cdots + X_n, \text{ where } \{ X_i \}_{i \in \mathbb{Z}^+} \text{ is an i.i.d. sequence of random variables.} \]

Then, by Cramér’s theorem, the probability law of \( Y_n/n \) satisfies the large deviation principle as long as

\[ \Lambda(\alpha) \equiv \lim_{n \to \infty} n^{-1} \log \mathbb{E} \exp \{ \langle \alpha, Y_n \rangle \} = \log \mathbb{E} \exp \{ \langle \alpha, X_1 \rangle \} \] (2.1)

is finite in a neighborhood of the origin. Since \( 0 \in \text{dom } \Lambda \), a slightly stronger condition would be to assume that \( \text{dom } \Lambda \) is open. As the right hand side of (2.1) is differentiable on the interior of its domain, “\( \text{dom } \Lambda \text{ open} \)” would also imply that \( \Lambda \) is differentiable on its full domain. Hence, “\( \text{dom } \Lambda \text{ open} \)” is sufficient to imply (H0). Next, observe by independence

\[ \Lambda_{\epsilon}(\alpha_u, \alpha_v) \equiv \lim_{n \to \infty} n^{-1} \log \mathbb{E} \exp \{ \langle \alpha_u, Y_m \rangle + \langle \alpha_v, Y_n - Y_m \rangle \} \]

\[ = \lim_{n \to \infty} n^{-1} \left\{ \log \mathbb{E} \exp \{ \langle \alpha_u, X_1 \rangle \}^m + \log \mathbb{E} \exp \{ \langle \alpha_v, X_1 \rangle \}^{n-m} \right\} \]

\[ = \epsilon \Lambda(\alpha_u) + (1 - \epsilon) \Lambda(\alpha_v). \] (2.2)
Therefore, (H1) always holds. Finally, note that for i.i.d. sums \( \mathcal{L}_0 \Lambda^* = \{ \lambda \mathbf{E} X_1 : \lambda \geq 0 \} \). Hence, (H2) holds as long as the set \( A \) avoids an arbitrarily thin \( \delta \)-cone about the mean ray \( \lambda \mathbf{E} X_1 : \lambda \geq 0 \), that is, as long as the mean of the process is directed away from the set \( A \).

If \( \{ Y_n \}_{n \in \mathbb{Z}} \) is a Markov-additive process as defined in Ney and Nummelin (1987a,b), then the situation is analogous, that is, (H0), (H1) and (H2) hold as long as the domain of \( \Lambda \) is open and the set \( A \) avoids a thin \( \delta \)-cone about the relevant mean vector. The situation is also analogous for general sequences satisfying the conditions of the Gärtner-Ellis theorem, except that in this case we do not automatically have (H1).

In our first result, we consider the decay of \( \mathbf{P} \{ T^x (A) \in C \} \) as \( \epsilon \to 0 \), where \( C \subset [0, \infty) \).

We show that this probability decays exponentially in \( \epsilon \), i.e.,

\[
\mathbf{P} \{ T^x (A) \in C \} \approx \exp \left\{ - \inf_{\tau \in C} I_A (\tau) / \epsilon \right\},
\]

with rate of decay described by a function \( I_A (\cdot) \) defined as follows.

**Definitions.** (i) For any set \( A \subset \mathbb{R}^d \), define \( I_A : [0, \infty) \to [0, \infty) \) by

\[
I_A (\tau) = \inf \left\{ \tau \Lambda^* (\frac{x}{\tau}) : x \in A \right\} \quad \text{for all } \tau > 0,
\]

and \( I_A (0) = \inf \{ (0^+ \Lambda^*) (x) : x \in A \} \), where \( 0^+ \Lambda^* \) is the recession function of \( \Lambda^* \).

With slight abuse of notation, we will also write \( \mathcal{T}_A (\cdot) \) for \( I_{\text{cl}} A (\cdot) \) and \( \mathbf{L}_A (\cdot) \) for \( I_{\text{int}} A (\cdot) \).

(ii) For any set \( C \subset [0, \infty) \), define \( J_C : \mathbb{R}^d \to [0, \infty) \) by

\[
J_C (x) = \inf \left\{ \tau \Lambda^* (\frac{x}{\tau}) : \tau \in C \right\} \quad \text{if } 0 \text{ in not a limit point of } C,
\]

and \( J_C (x) = \min \{ \inf_{\tau \in C - \{ 0 \}} \tau \Lambda^* (\frac{x}{\tau}), (0^+ \Lambda^*) (x) \} \) if 0 is a limit point of \( C \).

**Definition.** A set \( A \) will be called a semi-cone if \( x \in \partial A \implies \{ \lambda x : \lambda > 1 \} \subset \text{int } A \), that is, the ray generated by any point on the relative boundary of \( A \) is an interior ray of \( A \).

**Theorem 1.** Let \( Y_1, Y_2, \ldots \subset \mathbb{R}^d \) be a sequence of random variables satisfying (H0) and (H1), and let \( A \subset \mathbb{R}^d \) be a set satisfying (H2).

(i) **Upper bound.** For any set \( F \) which is closed in \([0, \infty)\),

\[
\lim_{\epsilon \to 0} \epsilon \log \mathbf{P} \{ T^x (A) \in F \} \leq - \inf_{\tau \in F} \mathcal{T}_A (\tau).
\]

(ii) **Lower bound.** If \( A \) is a semi-cone, then for any set \( G \) which is open in \([0, \infty)\),

\[
\lim_{\epsilon \to 0} \epsilon \log \mathbf{P} \{ T^x (A) \in G \} \geq - \inf_{\tau \in G} \mathbf{L}_A (\tau).
\]

**Remark 2.1.** (i) If \( 0 \in \text{dom } \Lambda^* \), then it is not necessary to take the infimum at the point \( \tau = 0 \) [Rockafellar (1970), Theorem 8.5]. Likewise, if \( A \) and \( C \) are convex and \( A \) is open and intersects \( \text{ri } (\bigcup_{\tau \in C} \tau \cdot \text{dom } \Lambda^* ) \), then we do not need to take the infimum at \( \tau = 0 \) (see Remark 3.3).
(ii) If cone $A \subset \text{dom } \Lambda^*$, then $\overline{T}_A(\tau) = L_A(\tau)$ for all $\tau > 0$. Therefore, under this assumption, the probability law of $T^\varepsilon(A)$ satisfies the large deviation principle with rate function $I_A$.

(iii) If $C \subset [0, \infty)$ is an interval and $A$ is a convex open semi-cone intersecting $\text{ri } (\bigcup_{\tau \in C} \tau \cdot \text{dom } \Lambda^*)$, then Theorem 1 reduces to

$$\lim_{\varepsilon \to 0} \varepsilon \log P \{ T^\varepsilon(A) \in C \} = -\inf_{\tau \in C} I_A(\tau). \tag{2.5}$$

In the special case $C = [0, \infty)$, equation (2.5) describes the probability that the sequence $\{Y_n\}$ ever hits the set $A$, which is Theorem 2.1 of Collamore (1996a). We note that Theorem 2.1 of Collamore (1996a) is proved under slightly weaker conditions; in particular, if $C = [0, \tau_0)$ for some $0 < \tau_0 \leq \infty$, then (H1) and the assumption that $A$ is a semi-cone can be dropped.

(iv) In general, the condition that $A$ is a semi-cone cannot be dropped to obtain the stated lower bound. However, if $A \subset \mathbb{R}^d$ is convex and the point $x_0$ given below in Lemma 2.2 (i) is an exposed point, in the sense that the ray joining 0 to $x_0$ does not intersect $\text{cl } A$ except at $x_0$, then this condition can be dropped.

Theorem 1 suggests that if $I_A(\tau)$ is minimized for a unique $\tau = \rho$, then the most likely normalized first passage time should be $T^\varepsilon(A) \approx \rho$.

**Lemma 2.2.** $Y_1, Y_2, \ldots \subset \mathbb{R}^d$ by a sequence of random variables having a differentiable logarithmic moment generating function, $\Lambda$, and let $A \subset \mathbb{R}^d$ be a convex set satisfying (H2), $A \cap \text{ri cone (dom } \Lambda^*) \neq \emptyset$. Then:

(i) $\inf_{x \in \text{cl } A} J_{[0, \infty)}(x)$ is achieved over $\text{cl } A$ at a unique point $x_0 \in \partial A$.

(ii) At some point $\alpha_0$ on the zero-set $\{ \alpha : \Lambda(\alpha) = 0 \}$, the gradient vector of $\Lambda$ points in the direction of $x_0$, that is,

$$x_0 = \rho \nabla \Lambda(\alpha_0), \text{ for some constant } \rho > 0.$$

(iii) $\inf_{\tau \in [0, \infty)} I_A(\tau)$ is achieved over $[0, \infty)$ at the unique point $\rho$ given in (ii).

A stronger version of this lemma will be proved below in Theorems 3.4, 3.7 and 6.1. Also see Remarks 3.3 and 3.5 and the discussion just prior to Theorem 6.1.

**Theorem 2.** Let $Y_1, Y_2, \ldots \subset \mathbb{R}^d$ be a sequence of random variables satisfying (H0) and (H1). Let $A$ be a convex open set satisfying (H2), $A \cap \text{ri cone (dom } \Lambda^*) \neq \emptyset$. Then for any $\gamma > 0$,

$$\lim_{\varepsilon \to 0} P \{ |T^\varepsilon(A) - \rho| > \gamma | T^\varepsilon(A) < \infty \} = 0, \tag{2.6}$$

where $\rho$ is the positive constant appearing in Lemma 2.2 (iii).

Since the rate function in equation (2.5) for the interval $C = [0, \infty)$ is

$$\inf_{\tau \in [0, \infty)} I_A(\tau) \equiv \inf_{x \in A} \left\{ \inf_{\tau > 0} \tau \Lambda^*(\frac{x}{\tau}), (0^+ \Lambda^*)(x) \right\} \equiv \inf_{x \in A} J_{[0, \infty)}(x),$$
Another natural consequence of Lemma 2.2 is the following.

**Theorem 3.** Let $Y_1, Y_2, \ldots \in \mathbb{R}^d$ be a sequence of random variables satisfying (H0) and (H1). Let $A$ be a convex open set satisfying (H2), $A \cap \text{ri cone (dom } \Lambda^*) \neq \emptyset$. Then for any $\gamma > 0$,

$$
\lim_{\varepsilon \to 0} \mathbb{P} \left\{ \left\| Y^\varepsilon_{T^\varepsilon(A)} - x_0 \right\| > \gamma \mid T^\varepsilon(A) < \infty \right\} = 0,
$$

where $x_0$ is the element of $\partial A$ appearing in Lemma 2.2 (i).

**Remark 2.3.** Some of the conditions in Theorems 1, 2 and 3 can be slightly weakened, as follows.

(i) Let

$$
T^\varepsilon_N(A) = \varepsilon \cdot \inf \{ n \geq N : Y^\varepsilon_n \in A \},
$$

that is, the first time after an initial time $N$ that $\{Y^\varepsilon_n\}_{n \in \mathbb{Z}^+}$ hits $A$. If $A$ is a convex open set and $N$ is suitably large, then Theorem 1 (i), 2 and 3 hold for $T^\varepsilon_N(A)$ without assuming (H1). If $A$ is a general set, then these theorems hold for $T^\varepsilon_N(A)$, some $N_0 \geq 1$, with the weaker condition (H1') of Collamore (1996a, b) in place of (H1). For details, see Collamore (1996b).

(ii) If $A$ is a general set, then Theorems 2 and 3 hold provided that: (a) $\inf_{x \in A} J_{[0, \infty)}(x)$ is achieved over $\text{cl } A$ at a unique point $x_0$, and (b) the infimum in the definition of $J_{[0, \infty)}$ is the same over $\text{int } A$ as it is over $\text{cl } A$ [as is the case, e.g., when $A$ is open and contained in $\text{int cone (dom } \Lambda^*)$].

**Example 2.4.** First we consider the classical ruin model studied e.g. in Cramér (1954), namely assume

$$
Y_t = ct - \sum_{i=1}^{N(t)} X_i,
$$

where $N(t)$ is a Poisson($\lambda$) process, $\{X_i\}_{i \in \mathbb{Z}^+} \subset \mathbb{R}$ is an independent sequence of random variables, and $c - \lambda E X_1 = E Y_1 > 0$. For simplicity, assume that the distribution of $X_i$ is exponential ($\theta$). Let $A$ denote the interval $(-\infty, -1)$ and consider

$$
T^\varepsilon(A) = \varepsilon \cdot \inf \{ n \in \mathbb{Z}_+: Y_n < \frac{1}{\varepsilon} \}. \quad (2.9)
$$

The logarithmic moment generating function for the discrete sequence $\{Y_n\}_{n \in \mathbb{Z}^+}$ is

$$
\Lambda(\alpha) = \left\{ \begin{array}{cc}
-\frac{\lambda \alpha}{1 + \alpha} + c \alpha & \text{for all } \alpha > -\frac{1}{\theta}, \\
\infty & \text{otherwise}. \end{array} \right. \quad (2.10)
$$

It follows that

$$
I_A(\tau) = \tau \Lambda^*(\frac{\tau}{\theta})|_{x=-1} = \left( \sqrt{1 + \frac{c\tau}{\theta}} - \sqrt{\lambda \tau} \right)^2, \quad \text{for all } \tau > 0, \quad (2.11)
$$

7
\[ I_A(\tau) = \inf_{x \in A} \tau A^*(x) = \inf_{x \in A} \left[ \frac{\tau x}{\tau} - \mu, S^{-1}(\frac{x}{\tau} - \mu) \right], \quad \text{for all } \tau > 0. \]
For example, if \( \mu = -\frac{1}{\sqrt{d}}(1, \ldots , 1) \), \( S = I \) [the identity matrix], and \( A = \{(x_1, \ldots , x_d) : x_i > 1\} \), then \( I_A(\tau) = \frac{e}{2} \cdot d \left( \frac{1}{\sqrt{d}} + \frac{1}{\sqrt{\tau}} \right)^2 \), which, among other things, has a minimum value at \( \rho = \sqrt{d} \). The existence and computation of this minimum value [corresponding to the most likely normalized first passage time] can also be obtained from Theorem 2. By symmetry, the unique element \( x_0 \in \partial A \) of Lemma 2.2 (i) is \((1, \ldots , 1)\). Then the element \( \alpha_0 \in \partial(\xi_0 A) \) of Lemma 2.2 (ii) is specified by the condition that \( \nabla \Lambda(\alpha) \) is parallel to \( x_0 \). By (2.15) it follows that \( \alpha_0 = \frac{2}{\sqrt{d}}(1, \ldots , 1) \) and then \( \nabla \Lambda(\alpha_0) = \frac{1}{\sqrt{d}}(1, \ldots , 1) \). Therefore, by Theorem 2, the most likely normalized first passage time is \( \rho = \sqrt{d} \).

3 Preliminary Results from Convex Analysis

Notation:
\[
\mathcal{H}^+(\alpha, t) = \{x \in \mathbb{R}^d : \langle \alpha, x \rangle \geq t\}, \text{ for all } \alpha \in \mathbb{R}^d \text{ and } t \in \mathbb{R};
\]
\[
\mathcal{H}^-(\alpha, t) = \{x \in \mathbb{R}^d : \langle \alpha, x \rangle \leq t\}, \text{ for all } \alpha \in \mathbb{R}^d \text{ and } t \in \mathbb{R};
\]
\[
S + T = \{s + t : s \in S, t \in T\}, \text{ for all sets } S \text{ and } T.
\]

For any set \( S \), let \( \text{ri } S, \partial S \) denote the relative interior of \( S \), relative boundary of \( S \), respectively.

For any function \( f \), let \( f^*(\cdot), \text{ dom } f, \text{ cl } f, \text{ epi } f, \text{ and } \partial f(\cdot) \) denote the convex conjugate of \( f \), the domain of \( f \), the closure of \( f \), the epigraph of \( f \), and the subgradient set of \( f \), respectively.

For any set \( S \), let \( 0^+S \) denote the recession cone of \( S \); and for any function \( f \), let \( 0^+f(\cdot) \) denote the recession function of \( f \). [For definitions, see Rockafellar (1970).]

Our main objective in this section is to develop the convexity properties of the following two functions.

Definitions. Let \( \Lambda \) denote the logarithmic moment generating function, as introduced in Section 2.

(i) For any convex set \( C \subset [0, \infty) \), let
\[
\Gamma_C(\alpha) = \sup_{\tau \in C} \tau \Lambda(\alpha).
\]

(ii) For any convex set \( \mathcal{C} \subset \{(\tau_u, \tau_v) : \tau_v \geq \tau_u \geq 0\} \), let
\[
\Gamma_{\mathcal{C}}(\alpha_u, \alpha_v) = \sup_{(\tau_u, \tau_v) \in \mathcal{C}} \left\{ \tau_u \Lambda(\alpha_u) + (\tau_v - \tau_u)\Lambda(\alpha_v) \right\}.
\]

In the next two theorems, we establish the relevance of the functions \( \Gamma_C(\cdot) \) and \( \Gamma_{\mathcal{C}}(\cdot) \) by relating them to the rate functions \( I_A(\cdot) \) and \( J_r(\cdot) \) introduced just prior to Theorem 1.

Theorem 3.1. Let \( \Xi \) be a convex set contained in the positive orthant \( \{(\xi_1, \ldots , \xi_k) : \xi_1 > 0, \ldots , \xi_k > 0\} \).

(i) If \( f : \mathbb{R}^d \to \mathbb{R} \) is a convex function, then the function
\[
F(x_1, \ldots , x_k) = \inf_{(\xi_1, \ldots , \xi_k) \in \Xi} \left\{ \xi_1 f\left(\frac{x_1}{\xi_1}\right) + \cdots + \xi_k f\left(\frac{x_k}{\xi_k}\right) \right\}
\]
is also convex.

(ii) If \( f : \mathbb{R}^d \to \mathbb{R} \) is a closed convex function, then the convex conjugate of

\[
F(\alpha_1, \ldots, \alpha_k) = \sup_{(\xi_1, \ldots, \xi_k) \in \Xi} \left\{ \xi_1 f(\alpha_1) + \cdots + \xi_k f(\alpha_k) \right\}
\]

is cl \( G \), where

\[
G(x_1, \ldots, x_k) = \inf_{(\xi_1, \ldots, \xi_k) \in \Xi} \left\{ \xi_1 f^*(\frac{x_1}{\xi_1}) + \cdots + \xi_k f^*(\frac{x_k}{\xi_k}) \right\}.
\]

**Proof.** (i) Define

\[
F_\xi(x_1, \ldots, x_k) = \xi_1 f\left(\frac{x_1}{\xi_1}\right) + \cdots + \xi_k f\left(\frac{x_k}{\xi_k}\right) \quad \text{and} \quad \mathfrak{F} = \bigcup_{(\xi_1, \ldots, \xi_k) \in \Xi} \text{epi } F_\xi.
\]

Then evidently

\[
F(x) = \inf \{ \mu : (x, \mu) \in \mathfrak{F} \}. \tag{3.1}
\]

To show that \( \mathfrak{F} \) is convex, note that the epigraph of \( x \mapsto \lambda f(x/\lambda) \) is \( \lambda \text{ (epi } f) \), for all \( \lambda > 0 \).

Letting

\[
\mathfrak{F}_i = \left\{ (x_1, \ldots, x_k, \mu) : (x_i, \mu) \in \text{epi } f \text{ and } x_j = 0 \text{ for } j \neq i \right\} \subset \mathbb{R}^{kd+1}, \tag{3.2}
\]

it follows that

\[
\text{epi } F_\xi = \xi_1 \mathfrak{F}_1 + \cdots + \xi_k \mathfrak{F}_k. \tag{3.3}
\]

Now let \( f_u, f_v \in \mathfrak{F} \) and \( 0 < \lambda < 1 \). Then by the definition of \( \mathfrak{F} \) and equation (3.3):

\[
f_u = \xi_1 f_1^{(u)} + \cdots + \xi_k f_k^{(u)} \quad \text{for some } \xi^{(u)} \in \Xi \text{ and } f_i^{(u)} \in \mathfrak{F}, i = 1, \ldots, k; \quad \text{and similarly}
\]

\[
f_v = \xi_1 f_1^{(v)} + \cdots + \xi_k f_k^{(v)} \quad \text{for some } \xi^{(v)} \in \Xi \text{ and } f_i^{(v)} \in \mathfrak{F}, i = 1, \ldots, k.
\]

Then

\[
\lambda f_u + (1 - \lambda) f_v = \left( \lambda \xi_1 f_1^{(u)} + (1 - \lambda) \xi_1 f_1^{(v)} \right) + \cdots
\]

\[
= \xi_1 \left( \frac{\lambda \xi_1^{(u)}}{\xi_1^{(u)}} f_1^{(u)} + \frac{(1 - \lambda) \xi_1^{(v)}}{\xi_1^{(v)}} f_1^{(v)} \right) + \cdots, \tag{3.4}
\]

where \( \xi_1 = \lambda \xi_1^{(u)} + (1 - \lambda) \xi_1^{(v)} \) and so on for \( \xi_2, \ldots, \xi_k \). On the last line of (3.4), the two scalars inside the brackets sum to one; hence the convexity of \( \mathfrak{F} \) implies that this quantity in brackets is an element of \( \mathfrak{F}_1 \), and so on for the indeces \( 2, \ldots, k \). Also, the convexity of \( \Xi \) implies that \( (\xi_1, \ldots, \xi_k) \in \Xi. \) Therefore,

\[
\lambda f_u + (1 - \lambda) f_v \in \xi_1 \mathfrak{F}_1 + \cdots + \xi_k \mathfrak{F}_k = \text{epi } F_\xi \in \mathfrak{F}. \tag{3.5}
\]

We conclude that \( \mathfrak{F} \) is convex. The convexity of \( F \) then follows from (3.1) and Theorem 5.3 of Rockafellar (1970).

(ii) Define

\[
F_\xi(\alpha_1, \ldots, \alpha_k) = \xi_1 f(\alpha_1) + \cdots + \xi_k f(\alpha_k). \tag{3.6}
\]
Then the convex conjugate of $F_\xi$ is
\[
F_\xi^*(x_1, \ldots, x_k) = \xi_1 f^\ast\left(\frac{x_1}{\xi_1}\right) + \cdots + \xi_k f^\ast\left(\frac{x_k}{\xi_k}\right),
\]
and an affine function $h : x \mapsto \langle \alpha, x \rangle - \mu$ minorizes $G \iff h$ minorizes $F_\xi^*$ for all $\xi \in \Xi$.
By definition of the convex conjugate and Theorem 12.2 of Rockafellar (1970), this occurs
$\iff (\alpha, \mu) \in \text{epi } F_\xi$ for all $\xi \in \Xi$; in other words, $\iff (\alpha, \mu) \in \text{epi } F$. Since $G$ is convex, by (i), we conclude $F = G^\ast$. Hence $F^\ast = \text{cl } G$ [Rockafellar (1970), Theorem 12.2]. $\square$

Next we identify the function cl $G$ of the previous theorem.

Theorem 3.2. Let $f : \mathbb{R}^d \to \mathbb{R}$ be a closed proper convex function with $f(0) > 0$, and let
$\Xi$ be a convex set contained in the positive orthant $\{(\xi_1, \ldots, \xi_k) : \xi_1 > 0, \ldots, \xi_k > 0\}$. Let
$(f \lambda)(x) = \lambda f(x/\lambda)$, for all $\lambda > 0$ and $x \in \mathbb{R}^d$, and let
\[
F(x_1, \ldots, x_k) = \inf_{(\xi_1, \ldots, \xi_k) \in \Xi} \{ (\xi_1 f)(x_1) + \cdots + (\xi_k f)(x_k) \}.
\]
Then
\[
\text{cl } F(x_1, \ldots, x_k) = \inf_{(\xi_1, \ldots, \xi_k) \in \Xi} \{ (\xi_1 f)(x_1) + \cdots + (\xi_k f)(x_k) \},
\]
where $\Xi = \text{cl } \Xi$ but with each $\xi_i = 0$ replaced with $\xi_i = 0^+$ [so that the infimum is taken in this case over $0^+ f$, the recession function of $f$].

Proof. Let $K \subset \mathbb{R}^{d+2}$ be the convex cone generated by $\{(1, y) : y \in \text{epi } f\}$. Since $f$ is a closed proper convex function, it follows that
\[
\text{cl } K = \{ (\lambda, y) : \lambda > 0, \ y \in \lambda(\text{epi } f) \} \cup \{ (0, y) : y \in 0^+(\text{epi } f) \} \quad (3.8)
\]
[Rockafellar (1970), Theorem 8.2]. Define
\[
H = \left\{ (\xi_1, y_1, \ldots, \xi_k, y_k) : (\xi_1, \ldots, \xi_k) \in \Xi \text{ and } y_i \in \mathbb{R}^{d+1}, \ i = 1, \ldots, k \right\}
\]
and
\[
L = (K \times \cdots \times K) \cap H \subset \mathbb{R}^{k(d+2)}.
\]
We study the image of the convex set $L$ under the transformation
\[
A : (\xi_1, y_1, \ldots, \xi_k, y_k) \to (x_1, \ldots, x_k, \mu_1 + \cdots + \mu_k), \quad \xi_i \in \mathbb{R} \text{ and } y_i = (x_i, \mu_i) \in \mathbb{R}^d \times \mathbb{R}.
\]
It follows directly from the definitions that
\[
A(L) = \{(x_1, \ldots, x_k, \mu_1 + \cdots + \mu_k) : (x_i, \mu_i) \in \xi_i \text{ (epi } f) \text{ and } (\xi_1, \ldots, \xi_k) \in \Xi \},
\]
\[
\text{cl } (A(L)) = \text{cl } (\text{epi } F). \quad (3.9)
\]
Since $\text{cl } L = (\text{cl } K \times \cdots \times \text{cl } K) \cap \text{cl } H$, these definitions and (3.8) also imply
\[
A(\text{cl } L) = \{(x_1, \ldots, x_k, \mu_1 + \cdots + \mu_k) : (x_i, \mu_i) \in \xi_i \text{ (epi } f) \text{ and } (\xi_1, \ldots, \xi_k) \in \Xi \}, \quad (3.10)
\]
where $\hat{\Xi} = \text{cl} \Xi$ but with $\xi = 0$ replaced with $\xi_i = 0^+$ [so that for such $\xi_i$ we take $(x_i, \mu_i) \in 0^+ (\text{epi } f)$, the recession cone of epi $f$]. Finally, note $\text{cl} A(L) = A(\text{cl} L)$ (Rockafellar (1970), Theorem 9.1, since $f(0) \neq 0$ implies that the only point of $0^+ (\text{cl} L)$ which is mapped by $A$ to zero is zero itself). Thus we conclude

$$\text{cl} \left( \text{epi } F \right) = \left\{ (x_1, \ldots, x_k, \mu_1 + \cdots + \mu_k) : (x_i, \mu_i) \in \xi_i \left( \text{epi } f \right) \text{ and } (\xi_1, \ldots, \xi_k) \in \hat{\Xi} \right\}.$$  

(3.11)

Since epi $(\xi_i f)$ is $\xi_i \left( \text{epi } f \right)$ and $0 + \left( \text{epi } f \right)$, the theorem follows from (3.11). $\square$

**Remark 3.3.** We now apply Theorems 3.1 and 3.2 to relate $\Gamma_C^\ast$ and $\Gamma_C$ to the rate functions $I_A$ and $J_C$.

(i) Suppose $C \subset [0, \infty)$ is convex. If $0$ is a limit point of $C$, then it follows from Theorems 3.1 and 3.2 that

$$\Gamma_C^\ast(x) = \text{cl } \left\{ \inf \{ \tau \Lambda^\ast \left( \frac{x}{\tau} \right) \} : \tau \in C \} = \left\{ \inf \{ \tau \Lambda^\ast \left( \frac{x}{\tau} \right) + (0^+ \Lambda^\ast)(x) \} : \tau \in C \} \right\}. \quad (3.12)$$

If $0$ is not a limit point of $C$, then $(0^+ \Lambda^\ast)(x)$ may be dropped from the infimum on the right of (3.12). Thus we obtain

$$\Gamma_C^\ast(x) = J_C(x) \quad \text{and} \quad \inf_{x \in A} \Gamma_C^\ast(x) = \inf_{\tau \in \text{cl } C} \inf_{x \in A} I_A(\tau), \quad (3.13)$$

for any $A \subset \mathbb{R}^d$.

Under certain circumstances, it is not necessary to include the recession function when taking the infimum on the right of the second equation of (3.13). For example, if $A$ is a convex open set intersecting $\text{ri } D_C$, where

$$D_C = \bigcup_{\tau \in C} \tau \text{ dom } \Lambda^\ast,$$

then $\inf_{x \in A} \Gamma_C^\ast(x) = \inf_{x \in A \cap \text{ri } D_C} \Gamma_C^\ast(x)$. Since $\Gamma_C^\ast(x) = \inf_{\tau \in C} \tau \Lambda^\ast(x/\tau)$ on $\text{ri } D_C$, by (3.12), we see that we do not need to include the recession function when computing $\inf_{\tau \in C} I_A(\tau)$ in this case.

(ii) Let $C \subset \{ (\tau_u, \tau_v) : \tau_v \geq \tau_u \geq 0 \}$ be convex, and let

$$J(\tau_u, \tau_v) = \inf_{(\tau_u, \tau_v) \in C} \left\{ \tau_u \Lambda^\ast \left( \frac{x_u}{\tau_u} \right) + (\tau_v - \tau_u)\Lambda^\ast \left( \frac{x_v}{\tau_v - \tau_u} \right) \right\}.$$ 

Then $\Gamma_C^\ast(x) = \text{cl } J(x)$. The closure can be removed e.g. if cl $C$ does not intersect the $x_u$-axis or the $x_v$-axis; otherwise, the infimum must be taken in a slightly broader sense, as described in Theorem 3.2.

**Theorem 3.4.** Let $f : \mathbb{R}^d \to \mathbb{R}$ be a closed proper convex function, and let $\mathcal{E}$ be a subset of $\mathbb{R}^d$. Assume $D \cap L_f$ is nonempty and bounded for some $\alpha$ and some $D \supset \mathcal{D}$. Then:

(i) There exists a point $x_0 \in \text{cl } \mathcal{E}$ such that $\inf_{x \in \mathcal{E}} f(x) = f(x_0)$.
(ii) If \( \mathcal{E} \) intersects \( \text{ri}(\text{dom } f) \) and either (a) \( \mathcal{E} \) is convex or (b) \( \text{cl } \mathcal{E} \cap \partial(\text{dom } f) = \emptyset \), then there exists a point \( \alpha_0 \in \partial f(x_0) \).

(iii) If \( \mathcal{E} \) is a convex set intersecting \( \text{ri}(\text{dom } f) \), then the point \( \alpha_0 \) in (ii) actually determines a separating hyperplane. That is, if \( a = \inf_{x \in \mathcal{E}} f(x) \), then for some \( t \in \mathbb{R} \) we have \( \mathcal{E} \subset \mathcal{H}^+(\alpha_0, t) \) and \( \mathcal{L}_a f \subset \mathcal{H}^-(\alpha_0, t) \).

**Proof.** (i) Let \( \tilde{f} = f \) on \( \text{cl } \mathcal{D} \) and \( \tilde{f} = \infty \) on \( (\text{cl } \mathcal{D})^c \). Then \( \mathcal{L}_\alpha \tilde{f} \) is compact for all \( \alpha \) [Rockafellar (1970), Corollary 8.7.1]. Hence (i) follows from the lower semicontinuity of \( \tilde{f} \).

(ii)-(iii) For the convex case, see Lemma 3.7 of Collamore (1996b) or Lemma 3.2 of Collamore (1996a). [These carry over with minor modifications to the slightly more general problem stated here.] For the nonconvex case [where \( \text{cl } \mathcal{E} \cap \partial(\text{dom } f) = \emptyset \)], see Theorem 23.4 of Rockafellar (1970). □

**Remark 3.5.** (i) In Theorem 3.4 it is assumed that \( \mathcal{D} \cap \mathcal{L}_\alpha f \) is bounded for some \( \alpha \) and some \( \mathcal{D} \). We now discuss the nature of this hypothesis in the context of the functions \( \Gamma^*_C \) and \( \Gamma^*_\mathcal{E} \) and the hypotheses (H0)–(H2).

Under hypothesis (H0), the logarithmic moment generating function, \( \Lambda \), is assumed to be differentiable. Hence \( \Lambda^* \) is essentially strictly convex [Rockafellar (1970), Theorem 26.3], which implies that \( \mathcal{L}_0 \Lambda^* \) is compact. If \( \mathcal{C} \) and \( \mathcal{E} \) are convex, it follows by Theorem 3.1 that \( \mathcal{L}_0 \Gamma^*_\mathcal{C} = \{ \tau x : \tau \in \text{cl } \mathcal{C}, x \in \mathcal{L}_0 \Lambda^* \} \) and \( \mathcal{L}_0 \Gamma^*_\mathcal{E} = \{ (\xi_ux_u, (\xi_v-\xi_u)x_v) : (\xi_u, \xi_v) \in \text{cl } \mathcal{C}, (x_u, x_v) \in \mathcal{L}_0 \Lambda^* \} \). Hence the zero level sets of \( \Gamma^*_C \) and \( \Gamma^*_\mathcal{E} \) are bounded for bounded convex intervals \( \mathcal{C} \) and \( \mathcal{E} \). Thus, for such intervals, Theorem 3.4 holds with no restriction on \( \mathcal{E} \).

If the interval \( \mathcal{C} \subset [0, \infty) \) is unbounded, then \( \Gamma^*_C \geq \Gamma^*_{[0, \infty)} \) has compact level sets on \( (\text{cone } \mathcal{B}_{\delta})^c \), for any \( \delta > 0 \). To demonstrate this fact, we note by Lemma 3.1 of Collamore (1996a) that

\[
\inf \{ \Gamma^*_{[0, \infty)}(x) : x \in (\text{cone } \mathcal{B}_{\delta})^c \text{ and } \|x\| = 1 \} = t, \text{ for some } t > 0. \tag{3.14}
\]

Also, by definition,

\[
\Gamma^*_{[0, \infty)}(x) = \sup_{\alpha \in \mathbb{R}^d} \{ \langle \alpha, x \rangle - 1_{\mathcal{L}_\alpha \Lambda}(\alpha) \} = \sup_{\alpha \in \mathbb{R}^d} \langle \alpha, x \rangle, \tag{3.15}
\]

where \( 1_{\mathcal{L}_\alpha \Lambda}(\cdot) \) is the indicator function on \( \mathcal{L}_\alpha \Lambda \). Hence \( \Gamma^*_{[0, \infty)}(\lambda x) = \lambda \Gamma^*_{[0, \infty)}(x) \) for all \( \lambda > 0 \) and \( x \in \mathbb{R}^d \), i.e., \( \Gamma^*_{[0, \infty)} \) is a positively homogeneous function. Using the positive homogeneity of \( \Gamma^*_{[0, \infty)} \) in conjunction with (3.14), we obtain that for any given \( a < \infty \),

\[
\inf \{ \Gamma^*_{[0, \infty)}(x) : x \in (\text{cone } \mathcal{B}_{\delta})^c \text{ and } \|x\| \geq K \} \geq a, \text{ for a sufficiently large constant } K. \tag{3.16}
\]

We conclude that Lemma 3.4 applies for any set \( \mathcal{E} = A \), where \( A \) satisfies hypothesis (H2).

(ii) If \( \mathcal{E} = A \), where \( A \) satisfies hypothesis (H2), then \( A \subset (\text{cone } \mathcal{B}_{\delta})^c \). Also, if \( \mathcal{C} \subset [0, \infty) \) is convex, then by Theorem 3.1 we have \( \mathcal{L}_0 \Gamma^*_C = \{ \tau x : \tau \in \text{cl } \mathcal{C}, x \in \mathcal{L}_0 \Lambda^* \} \subset (\text{cone } \mathcal{B}_{\delta})^c \). Therefore, it follows by the convexity of \( \Gamma^*_C \) that \( x_0 \) is a boundary point of \( A \).

To motivate our next result, note by Theorem 23.5 of Rockafellar (1970) that \( \alpha_0 \in \partial f(x_0) \iff x_0 \in \partial f^*(\alpha_0) \). It is therefore of interest to characterize the set \( \partial f^*(\alpha_0) \). Next
we do this when \( f^* \) is the function \( F(\alpha) = \sup_{\xi \in \Xi} \{ \xi_1 f(\alpha_1) + \cdots + \xi_k f(\alpha_k) \} \) given earlier in Theorem 3.1.

**Theorem 3.6.** Let \( f : \mathbb{R}^d \to \mathbb{R} \) be a convex function which is differentiable on its domain; let \( \Xi \) be a convex set contained in the positive orthant \( \{(\xi_1, \ldots, \xi_k) : \xi_1 > 0, \ldots, \xi_k > 0\} \); and let \( F : \mathbb{R}^{kd} \to \mathbb{R} \) be defined by

\[
F(\alpha) = \sup_{\xi \in \Xi} f_\xi(\alpha),
\]

where

\[
f_\xi(\alpha_1, \ldots, \alpha_k) = \xi_1 f(\alpha_1) + \cdots + \xi_k f(\alpha_k) \quad \text{for} \quad \alpha_1, \ldots, \alpha_k \in \mathbb{R}^d.
\]

Assume \( \nabla f(\alpha_i) \) exists and is nonzero for each \( i \), and assume \( F \) is finite and lower semi-continuous at \( \alpha \). Then

\[
\partial F(\alpha) = \bigcup_{\xi \in \Xi_\alpha} \nabla f_\xi(\alpha), \tag{3.17}
\]

where \( \Xi_\alpha = \{ \xi \in \text{cl} \Xi : f_\xi(\alpha) = F(\alpha) \} \).

**Proof.** Let

\[
\mathfrak{F}_\alpha = \bigcup_{\xi \in \Xi_\alpha} \nabla f_\xi(\alpha)
\]

[the set given on the right of (3.17)], and define neighborhoods of the index set \( \Xi_\alpha \) and of \( \mathfrak{F}_\alpha \) as follows. For any \( \delta > 0 \), let

\[
\Xi_\alpha(\delta) = \{ \xi \in \text{cl} \Xi : f_\xi(\alpha) \geq F(\alpha) - \delta \} \quad \text{and} \quad \mathfrak{F}_\alpha^{(\delta)} = \bigcup_{\xi \in \Xi_\alpha(\delta)} \{ \nabla f_\xi(\tilde{\alpha}) : \|\tilde{\alpha} - \alpha\| \leq \delta \}.
\]

(\( \supset \)): Assume \( x \in \mathfrak{F}_\alpha \) and show \( x \in \partial F(\alpha) \).

If \( x \in \mathfrak{F}_\alpha \), then \( x = \nabla f_\xi(\alpha) \) for some \( \xi \in \Xi_\alpha \). Hence

\[
\sup_{\tilde{\alpha} \in \mathbb{R}^{kd}} \left\{ \langle \tilde{\alpha}, x \rangle - f_\xi(\tilde{\alpha}) \right\} = \left\{ \langle \alpha, x \rangle - f_\xi(\alpha) \right\} \tag{3.18}
\]

[Rockafellar (1970), Theorem 23.5]. Since the definition of \( F \) implies \( F(\tilde{\alpha}) \geq f_\xi(\tilde{\alpha}) \) for all \( \tilde{\alpha} \); and the definition of \( \Xi_\alpha \) implies \( F(\xi) = f_\xi(\alpha) \) for \( \xi \in \Xi_\alpha \); it follows that

\[
\sup_{\tilde{\alpha} \in \mathbb{R}^{kd}} \left\{ \langle \tilde{\alpha}, x \rangle - F(\tilde{\alpha}) \right\} = \left\{ \langle \alpha, x \rangle - F(\alpha) \right\}. \tag{3.19}
\]

Therefore, \( x \in \partial F(\alpha) \) [Rockafellar (1970), Theorem 23.5].

(\( \subset \)): Assume \( x \notin \mathfrak{F}_\alpha \) and show \( x \notin \partial F(\alpha) \).

Consider the set \( \mathfrak{F}_\alpha^{(\delta)} \) as \( \delta \downarrow 0 \). Note first that \( \{ \nabla f(\tilde{\alpha}) : \|\tilde{\alpha} - \alpha\| \leq \delta \} \) decreases to

\[\left\{ \left( \nabla f(\alpha_1), \ldots, \nabla f(\alpha_k) \right) \right\} \quad \text{as} \quad \delta \downarrow 0 \quad \text{[Rockafellar (1970), Corollary 25.5.1]} ; \text{and by assumption the elements} \quad \nabla f(\alpha_i) \quad \text{are nonzero for all} \ i \quad \text{. It follows that}
\]

\[
\mathfrak{F}_\alpha^{(\delta)} = \left\{ \left( \xi_1 \nabla f(\tilde{\alpha}_1), \ldots, \xi_k \nabla f(\tilde{\alpha}_k) \right) : \xi \in \Xi_\alpha^{(\delta)} \right\}
\]
decreases to
\[ F = n_1 r_f(\sim 1) \cdots k r_f(\sim k). \]

It is easily verified that \( \Xi_\alpha \) is convex, hence so is \( \overline{F}_\alpha \). Thus we conclude
\[ \text{conv } \overline{F}_\alpha^{(\delta)} \downarrow \text{conv } \overline{F}_\alpha = \overline{F}_\alpha \text{ as } \delta \downarrow 0. \tag{3.20} \]

Therefore, \( x \notin \overline{F}_\alpha \implies x \notin \text{conv } \overline{F}_\alpha^{(\delta)} \) for \( \delta \leq \delta_0 \).

Fix \( \delta \leq \delta_0 \). Then \( \{x\} \) and \( \text{conv } \overline{F}_\alpha^{(\delta)} \) are disjoint convex sets; consequently, there exists a strongly separating hyperplane; that is, 
\[ \text{conv } \overline{F}_\alpha^{(\delta)} \subset \mathcal{H}^-(z, t - \epsilon) \text{ and } \{x\} \subset \mathcal{H}^+(z, t) \tag{3.21} \]
for some \( z \in \mathbb{R}^{kd}, t \in \mathbb{R}, \) and \( \epsilon > 0 \). Consider the derivative of \( F \) in the direction of \( z \). By definition this is
\[ F'(\alpha; z) \equiv \lim_{\lambda \downarrow 0} \frac{F(\alpha + \lambda z) - F(\alpha)}{\lambda}. \tag{3.22} \]

Next observe that for \( \lambda \geq 0 \) sufficiently small:
\[ F(\alpha + \lambda z) = \sup_{\xi \in \Xi} f_\xi(\alpha + \lambda z) = \sup_{\xi \in \Xi^{(\delta)}} f_\xi(\alpha + \lambda z). \tag{3.23} \]

[Otherwise \( G(\hat{\alpha}) \equiv \sup \left\{ f_\xi(\hat{\alpha}) : \xi \in \Xi - \Xi^{(\delta)}_\alpha \right\} \) would satisfy \( G(\alpha + \lambda_i z) = F(\alpha + \lambda_i z) \) along a sequence \( \lambda_i \downarrow 0 \).]

Also, by definition of \( \Xi^{(\delta)}_\alpha \): \( G(\alpha) \leq F(\alpha) - \delta \). Since \( F \) is lower semicontinuous at \( \alpha \), it would follow that \( G \) is not convex. But \( G \) is a supremum of convex functions and hence \( G \) is convex. Contradiction.] It follows by (3.22) and (3.23) that
\[ F'(\alpha; z) \leq \lim_{\lambda \downarrow 0} \sup_{\alpha \in \Xi^{(\delta)}_\alpha} \left[ \frac{f_\xi(\alpha + \lambda z) - f_\xi(\alpha)}{\lambda} \right]. \tag{3.24} \]

By the mean value theorem, the quantity in brackets in (3.24) is \( \langle \nabla f_\xi(\hat{\alpha}), z \rangle \) for some \( \hat{\alpha} \in [\alpha, \alpha + \lambda z] \); and if \( \lambda \) is sufficiently small, then it follows by the definition of \( \overline{F}_\alpha^{(\delta)} \) that \( \nabla f_\xi(\hat{\alpha}) \in \overline{F}_\alpha^{(\delta)} \). Therefore, by (3.21) and (3.24) we obtain
\[ F'(\alpha; z) \leq t - \epsilon. \tag{3.25} \]

Hence by (3.21) and (3.25): \( F'(\alpha; z) < \langle x, z \rangle \). This implies \( x \notin \partial F(\alpha) \) [Rockafellar (1970), Theorem 23.2]. \( \Box \)

Of particular interest are the properties of
\[ \inf_{x \in A} \Gamma_{[0, \infty)}^*(x) = \inf_{x \in A} \min \left\{ \inf_{\tau > 0} \Lambda^*(\frac{x}{\tau}), \ (0^+ \Lambda^*)(x) \right\} = \inf_{\tau \in [0, \infty)} I_A(\tau), \]

namely, the rate function in (2.5) corresponding to the probability that the sequence \( Y_1, Y_2, \ldots \) ever hits the set \( A \subset \mathbb{R}^d \).
Theorem 3.7. Let $Y_1, Y_2, \ldots \in \mathbb{R}^d$ be a sequence of random variables having a differentiable logarithmic moment generating function, $\Lambda$, and let $A \subset \mathbb{R}^d$ be a convex set satisfying (H2), $A \cap \text{ri cone} \ (\text{dom } \Lambda^*) \neq \emptyset$. Let $x_0$ and $\alpha_0$ be given as in Theorem 3.4 when $f = \Gamma^{*}_{[0, \infty)}$ and $\mathcal{E} = A$. Then:

(i) $\alpha_0 \in \partial (\mathcal{L}_0 \Lambda)$ and $\Lambda(\alpha_0) = 0$.

(ii) There exists a constant $\rho > 0$ such that $x_0 = \rho \nabla \Lambda(\alpha_0)$.

(iii) The element $x_0$ is unique.

Proof. (i) Note $\Gamma^{*}_{[0, \infty)}(\alpha) \equiv \sup_{\tau \in [0, \infty)} \tau \Lambda(\alpha) = 1_{\mathcal{L}_0 \Lambda}(\alpha)$, where $1_{\mathcal{L}_0 \Lambda}(\cdot)$ is the indicator function on the set $\mathcal{L}_0 \Lambda$. Hence

$$
\Gamma^{*}_{[0, \infty)}(x_0) \equiv \sup_{\alpha \in \mathbb{R}^d} \{ \langle \alpha, x_0 \rangle - 1_{\mathcal{L}_0 \Lambda}(\alpha) \} = \sup_{\alpha \in \mathcal{L}_0 \Lambda} \langle \alpha, x_0 \rangle.
$$

(3.26)

Since (H2) $\implies x_0 \neq 0$, the supremum on the right can only be achieved on the boundary of $\mathcal{L}_0 \Lambda$. Hence $\alpha_0 \in \partial (\mathcal{L}_0 \Lambda)$. Since $\Lambda$ is differentiable at $\alpha_0$, it follows that $\Lambda(\alpha_0) = 0$.

(ii) This follows from Theorem 3.6. The constant $\rho$ is positive since (H2) $\implies x_0 \neq 0$.

(iii) Let $x_0^{(1)}, x_0^{(2)}$ be two such elements, and let $\alpha_0 \in \partial \Gamma^{*}_{[0, \infty)}(x_0^{(2)})$ denote the element obtained in Lemma 3.4 (ii) which corresponds to $x_0^{(2)}$. Let $a = \inf_{x \in \text{cl } A} \Gamma^{*}_{[0, \infty)}(x)$.

Since $\{x_0^{(1)}, x_0^{(2)}\} \subset \mathcal{L}_0 \Gamma^{*}_{[0, \infty)} \cap \text{cl } A$, it follows that both $x_0^{(1)}$ and $x_0^{(2)}$ lie on the hyperplane given in Theorem 3.4 (iii) which separates $\mathcal{L}_0 \Gamma^{*}_{[0, \infty)}$ and $\text{cl } A$. From this fact, together with the fact that $\alpha_0$ achieves the supremum on the right of (3.26), we obtain

$$
\langle \alpha_0, x_0^{(1)} \rangle = \langle \alpha_0, x_0^{(2)} \rangle = \sup_{\alpha \in \mathcal{L}_0 \Lambda} \langle \alpha, x_0 \rangle.
$$

(3.27)

Thus, both $x_0^{(1)}$ and $x_0^{(2)}$ belong to the normal cone to $\mathcal{L}_0 \Lambda$ at $\alpha_0$. This implies

$$
x_0^{(i)} = \rho_i \nabla \Lambda(\alpha_0), \quad i = 1, 2, \quad \text{for certain positive constants } \rho_1, \rho_2
$$

(3.28)

[Rockafellar (1970), Corollary 23.7.1. This corollary is applicable since (H2) $\implies \Lambda^*(0) > 0$, hence $\inf_{\alpha} \Lambda(\alpha) < 0$.] Therefore

$$
x_0^{(1)} = \rho_1 (\nabla \Lambda(\alpha_0)) = \rho_1 \left( \rho_2^{-1} x_0^{(2)} \right).
$$

(3.29)

Next observe by (3.26) that $\Gamma^{*}_{[0, \infty)}(x) = \sup_{\alpha \in \mathcal{L}_0 \Lambda} \langle \alpha, x \rangle$, which shows that the function $\Gamma^{*}_{[0, \infty)}$ is positively homogeneous, i.e., $\Gamma^{*}_{[0, \infty)}(\lambda x) = \lambda \Gamma^{*}_{[0, \infty)}(x)$ for all $\lambda, x$. Hence by (3.29)

$$
\Gamma^{*}_{[0, \infty)}(x_0^{(1)}) = \frac{\rho_1}{\rho_2} \Gamma^{*}_{[0, \infty)}(x_0^{(2)}).
$$

(3.30)

Since $x_0^{(1)}$ and $x_0^{(2)}$ both minimize $\Gamma^{*}_{[0, \infty)}$ over $\text{cl } A$, it follows from (3.30) that $(\rho_1/\rho_2) = 1$, and by (3.29) this implies $x_0^{(1)} = x_0^{(2)}$. □

4 Estimates for Occupation Probabilities

For any set $A \subset \mathbb{R}^d$, let

$$
P^\epsilon_C(A) = \mathbb{P} \{ Y_n^\epsilon \in A, \ n \in C/\epsilon \}, \quad \text{for all convex } C \subset [0, \infty).
$$
Thus e.g. if \( C = (\tau_1, \tau_2) \), then \( \mathbb{P}_C(A) \) is the probability that the normalized sequence \( \{Y_n^*\} \) hits \( A \subset \mathbb{R}^d \) at some time during the interval \( \epsilon^{-1}(\tau_1, \tau_2) \). For any set \( \mathfrak{A} \subset \mathbb{R}^{2d} \), let
\[
\mathbb{P}_C(\mathfrak{A}) = \mathbb{P}\left\{ \mathcal{Z}_{m,n}^\epsilon \in \mathfrak{A}, (m,n) \in C/\epsilon \right\}, \quad \text{for all convex } \mathcal{C} \subset \{(\tau_u, \tau_v) : \tau_v \geq \tau_u \geq 0\}.
\]
Thus e.g. if \( \mathcal{C} = (\tau_1, \tau_2) \times (\zeta_1, \zeta_2) \), then \( \mathbb{P}_C(\mathfrak{A}) \) is the probability that the normalized sequence \( Z_{m,n}^\epsilon \equiv (Y_m^*, Y_n^* - Y_m^*) \) hits \( \mathfrak{A} \subset \mathbb{R}^{2d} \) at some time during the interval \( \mathcal{C}/\epsilon \), i.e. for some \( m \in \epsilon^{-1}(\tau_1, \tau_2) \) and some \( n \in \epsilon^{-1}(\zeta_1, \zeta_2) \).

In this section we derive estimates for the “occupation probabilities” \( \mathbb{P}_C(A) \) and \( \mathbb{P}_C(\mathfrak{A}) \). Asymptotics for the hitting time \( T^*(A) \), i.e. the first time \( \{Y_n^*\} \) hits \( A \), will follow directly from these estimates.

**Notation.** First we recall the definitions of \( \Gamma_C \) and \( \Gamma_\mathcal{C} \) from the previous section. For any convex set \( C \subset [0, \infty) \), let
\[
\Gamma_C(\alpha) = \sup_{\tau \in C} \tau \Lambda(\alpha), \quad \text{for all } \alpha \in \mathbb{R}^d;
\]
and for any convex set \( \mathcal{C} \subset \{(\tau_u, \tau_v) : \tau_v \geq \tau_u \geq 0\} \), let
\[
\Gamma_\mathcal{C}(\alpha_u, \alpha_v) = \sup_{(\tau_u, \tau_v) \in \mathcal{C}} \left\{ \tau_u \Lambda(\alpha_u) + (\tau_v - \tau_u) \Lambda(\alpha_v) \right\}, \quad \text{for all } \alpha_u, \alpha_v \in \mathbb{R}^d.
\]
Also let
\[
\mathcal{H}_\mathcal{C}(\alpha, a) = \text{the open half-space } \left\{ x \in \mathbb{R}^{2d} : \langle \alpha, x \rangle > (a + \Gamma_\mathcal{C}(\alpha)) \right\}
\]
for all \( \alpha \in \mathbb{R}^{2d}, a \in \mathbb{R} \);
\[
\text{proj}(\mathfrak{A}) = \left\{ x_u \in \mathbb{R}^d : (x_u, x_v) \in \mathfrak{A} \right\} \bigcup \left\{ x_u + x_v \in \mathbb{R}^d : (x_u, x_v) \in \mathfrak{A} \right\}
\]
for any set \( \mathfrak{A} \subset \mathbb{R}^{2d} \).

**Theorem 4.1.** Let \( Y_1, Y_2, \ldots \subset \mathbb{R}^d \) be a sequence of random variables satisfying (H0) and (H1), and let \( A \subset \mathbb{R}^d \) be a set satisfying (H2). Let \( C \) be a convex subset of \( [0, \infty) \). Then
(i) Upper bound:
\[
\limsup_{\epsilon \to 0} \epsilon \log \mathbb{P}_C(A) \leq - \inf_{x \in \text{cl} A} \Gamma_C^*(x). \quad (4.1)
\]
(ii) Lower bound:
\[
\liminf_{\epsilon \to 0} \epsilon \log \mathbb{P}_C(A) \geq - \inf_{x \in \text{int} A} \Gamma_C^*(x). \quad (4.2)
\]

**Theorem 4.2.** Let \( Y_1, Y_2, \ldots \subset \mathbb{R}^d \) be a sequence of random variables satisfying (H0) and (H1), and let \( \mathfrak{A} \subset \mathbb{R}^{2d} \) be a set such that \( \text{proj}(\mathfrak{A}) \) satisfies (H2). Let \( \mathcal{C} \) be a convex subset of \( \{(\tau_u, \tau_v) : \tau_v \geq \tau_u \geq 0\} \), and assume \((0,0) \notin \text{cl} \mathcal{C} \). Then
(i) Upper bound:
\[
\limsup_{\epsilon \to 0} \epsilon \log \mathbb{P}_C(\mathfrak{A}) \leq - \inf_{x \in \text{cl} \mathfrak{A}} \Gamma_\mathcal{C}^*(x). \quad (4.3)
\]
(ii) **Lower bound:**

\[
\liminf_{\epsilon \to 0} \epsilon \log P_{\epsilon}^{C}(A) \geq - \inf_{x \in \text{int} \ A} \Gamma_{\epsilon}^{*}(x).
\] (4.4)

First we turn to the proof of Theorem 4.2 and then indicate how this proof can be modified to establish Theorem 4.1. The proof of the upper bound of Theorem 4.2 is dependent upon the following.

**Lemma 4.3.** Let \( Y_1, Y_2, \ldots \) be a sequence of random variables satisfying (H0) and (H1). Let \( C \) be a bounded convex subset of \( \{(\tau_u, \tau_v) : \tau_v \geq \tau_u \geq 0\} \), and assume \((0, 0) \notin \text{cl} \ C\). Then

\[
\limsup_{\epsilon \to 0} \epsilon \log P_{\epsilon}^{C}(\mathcal{H}(\alpha, a)) \leq -a.
\] (4.5)

**Proof of Lemma 4.3.** Let \( m, n \) denote the probability law of \( Z_{m,n} \), and define a transformed measure \( \tilde{\mu}_{m,n} \) as follows:

\[
\tilde{\mu}_{m,n}(F) = \int_{m} \exp \{ \langle \alpha, z \rangle - \Lambda_{m,n}(\alpha) \} \, d\mu_{m,n}(z),
\] (4.6)

for all measurable sets \( F \subset \mathbb{R}^{2d} \). Then by definition:

\[
P \{ Z_{m,n}^{\epsilon} \in \mathcal{H}_{\epsilon}(\alpha, a) \} = \int_{\mathbb{R}^{2d}} \exp \{ - (\langle \alpha, z \rangle - \Lambda_{m,n}(\alpha)) \} \, d\tilde{\mu}_{m,n}(z)
\]

\[
= E \left[ \exp \left\{ - \left( \langle \alpha, \tilde{Z}_{m,n}^{\epsilon} \rangle - \Lambda_{m,n}(\alpha) \right) \right\} ; \ \tilde{Z}_{m,n}^{\epsilon} \in \mathcal{H}_{\epsilon}(\alpha, a) \right],
\] (4.7)

where \( \tilde{Z}_{m,n}^{\epsilon} \) is a random variable having distribution \( \tilde{\mu}_{m,n} \) and \( \tilde{Z}_{m,n}^{\epsilon} = \epsilon \tilde{Z}_{m,n} \). We replace \( \Lambda_{m,n} \) with a limiting generating function, \( \Lambda^{m}_{\epsilon} \), by introducing the ratio

\[
\mathcal{R}_{m,n} = \exp \left\{ \Lambda_{m,n}(\alpha) - n \Lambda^{m}_{\epsilon}(\alpha) \right\} ;
\] (4.8)

then (4.7) becomes

\[
P \{ Z_{m,n}^{\epsilon} \in \mathcal{H}_{\epsilon}(\alpha, a) \} = \mathcal{R}_{m,n} \cdot E \left[ \exp \left\{ - \left( \langle \alpha, \tilde{Z}_{m,n}^{\epsilon} \rangle - n \Lambda^{m}_{\epsilon}(\alpha) \right) \right\} ; \ \tilde{Z}_{m,n}^{\epsilon} \in \mathcal{H}_{\epsilon}(\alpha, a) \right].
\] (4.9)

The utility of this last representation is then evident from the following result, where it is shown that the random variable in this last expectation is deterministically bounded over \( \{ \tilde{Z}_{m,n}^{\epsilon} \in \mathcal{H}_{\epsilon}(\alpha, a) \} \) for \((m, n) \in \mathcal{C}/\epsilon\).

**Sublemma 1:** If \((m, n) \in \mathcal{C}/\epsilon \) and \( \tilde{Z}_{m,n}^{\epsilon} \in \mathcal{H}_{\epsilon}(\alpha, a) \), then

\[
\left\{ \langle \alpha, \tilde{Z}_{m,n}^{\epsilon} \rangle - n \Lambda^{m}_{\epsilon}(\alpha) \right\} > \frac{a}{\epsilon}.
\] (4.10)

**Proof.** By definition,

\[
\tilde{Z}_{m,n}^{\epsilon} \in \mathcal{H}_{\epsilon}(\alpha, a) \iff \left\{ \langle \alpha, \tilde{Z}_{m,n}^{\epsilon} \rangle - \Gamma_{\epsilon}(\alpha) \right\} > a
\]

\[
\iff \left\{ \langle \alpha, \tilde{Z}_{m,n}^{\epsilon} \rangle - \frac{1}{\epsilon} \Gamma_{\epsilon}(\alpha) \right\} > \frac{a}{\epsilon},
\] (4.11)
Thus the proof will be complete as soon as we show that, on the right side of (4.11), $\epsilon^{-1} \Gamma_{\epsilon}(\alpha)$ can be replaced with $n \Lambda \underline{\psi}(\alpha)$. To this end, observe that by (H1):

$$n \Lambda \underline{\psi}(\alpha) = m \Lambda(\alpha_u) + (n - m) \Lambda(\alpha_v), \quad \text{where } \alpha = (\alpha_u, \alpha_v).$$

Thus $(m, n) \in \mathcal{C}/\epsilon$ implies

$$n \Lambda \underline{\psi}(\alpha) \leq \epsilon^{-1} \sup_{(\tau_u, \tau_v) \in \mathcal{C}} \left\{ \tau_u \Lambda(\alpha_u) + (\tau_v - \tau_u) \Lambda(\alpha_v) \right\} \equiv \epsilon^{-1} \Gamma_{\epsilon}(\alpha).$$

Substituting this inequality into the right side of (4.11) gives

$$\left\{ \langle \alpha, Z_{m,n} \rangle - n \Lambda \underline{\psi}(\alpha) \right\} > \frac{a}{\epsilon}. \quad \Box$$

By Sublemma 1 and (4.9),

$$P \left\{ Z_{m,n}^t \in \mathcal{H}_{\epsilon}(\alpha, a) \right\} \leq \mathfrak{R}_{m,n} \cdot e^{-a/\epsilon} \quad \text{for } (m, n) \in \mathcal{C}/\epsilon.$$ 

Consequently, the probability that $Z_{m,n}^t$ enters $\mathcal{H}_{\epsilon}(\alpha, a)$ at some time $(m, n) \in \mathcal{C}/\epsilon$ is

$$P_{\epsilon} \left\{ \mathcal{H}_{\epsilon}(\alpha, a) \right\} \leq e^{-a/\epsilon} \sum_{(m,n) \in \mathcal{C}/\epsilon} \mathfrak{R}_{m,n}.$$ 

It follows that

$$\limsup_{\epsilon \to 0} \epsilon \log P_{\epsilon} \left\{ \mathcal{H}_{\epsilon}(\alpha, a) \right\} \leq -a + \limsup_{\epsilon \to 0} \max_{(m,n) \in \mathcal{C}/\epsilon} \{ \epsilon \log \mathfrak{R}_{m,n} \}.$$ 

Finally, the lemma is obtained by showing that the ratio $\mathfrak{R}_{m,n}$ can, in a suitable sense, be neglected.

**Sublemma 2:** $\limsup_{\epsilon \to 0} \max_{(m,n) \in \mathcal{C}/\epsilon} \{ \epsilon \log \mathfrak{R}_{m,n} \} = 0$.

**Proof.** Suppose false. Then there exists a sequence $\{ \epsilon_i \}_{i \in \mathbb{Z}_+}$ with $\epsilon_i \to 0$ as $i \to \infty$ and

$$\epsilon_i \log \mathfrak{R}_{m_i, n_i} \geq t > 0, \quad \text{some } (m_i, n_i) \in \mathcal{C}/\epsilon_i.$$ 

Note: $(m_i, n_i) \in \mathcal{C}/\epsilon_i$, where $\mathcal{C} \subset \{(\tau_u, \tau_v) : \tau_v \geq \tau_u \geq 0\}$ is bounded and does not have $(0,0)$ as a limit point. It follows that along a subsequence

$$n_i \to \infty \text{ and } \frac{m_i}{n_i} \to r \quad \text{as } i \to \infty, \quad \text{for some constant } r \in [0,1].$$ 

Then, along this subsequence,

$$\lim_{i \to \infty} \frac{\Lambda_{m_i, n_i}(\alpha)}{n_i} = \lim_{n_i \to \infty} \frac{1}{n_i} \log E \exp \left\{ \langle \alpha, Z_{m_i, n_i} \rangle \right\} \equiv \Lambda_t(\alpha).$$ 

Also, by (H1) and (4.18),

$$\lim_{i \to \infty} \Lambda \underline{\psi}(\alpha) = \lim_{i \to \infty} \left\{ \frac{m_i}{n_i} \Lambda(\alpha_u) + \left(1 - \frac{m_i}{n_i}\right) \Lambda(\alpha_v) \right\} = \Lambda_t(\alpha).$$
By (4.19) and (4.20) it follows that
\[
\limsup_{i \to \infty} \epsilon_i \log \mathcal{R}_{m_i,n_i} \equiv \limsup_{i \to \infty} \epsilon_i n_i \left\{ \frac{\Lambda_{m_i,n_i}(\alpha)}{n_i} - \Lambda_{m_i}(\alpha) \right\} = 0 \quad (4.21)
\]
[since \(\epsilon_i(m_i,n_i) \in \epsilon_i(\epsilon_i^{-1} \mathcal{C}) = \mathcal{C}\) implies \(\epsilon_i n_i \in \mathbb{Z}_+\) is bounded]. But (4.21) contradicts (4.17). \(\Box\)

**Proof of Theorem 4.2. Upper Bound.**

**Step 1:** The upper bound holds under the assumption that \(\mathfrak{A}\) and \(\mathcal{C}\) are bounded.

**Proof.** Let \(a < \inf_{x \in \text{cl} \mathfrak{A}} \Gamma_\varepsilon^*(x)\). Then for any \(x \in \text{cl} \mathfrak{A}\),
\[
\sup_{\alpha \in \mathbb{R}^{2d}} \{ \langle \alpha, x \rangle - \Gamma_\varepsilon(\alpha) \} \equiv \Gamma_\varepsilon^*(x) > a;
\]
(4.22)
hence for some \(\alpha_x \in \mathbb{R}^{2d}\),
\[
x \in \mathcal{H}_\varepsilon(\alpha_x, a) \equiv \left\{ z : \langle \alpha_x, z \rangle - \Gamma_\varepsilon(\alpha) > a \right\}.
\]
(4.23)
By (4.23), \(\{\mathcal{H}_\varepsilon(\alpha_x, a)\}_{x \in \text{cl} \mathfrak{A}}\) is an open cover for the compact set \(\text{cl} \mathfrak{A}\); hence there exists a finite subcover: \(\mathcal{H}_\varepsilon(\alpha_{x_1}, a), \ldots, \mathcal{H}_\varepsilon(\alpha_{x_l}, a)\); and
\[
\mathbb{P}_\varepsilon^e(\mathfrak{A}) \leq \sum_{i=1}^l \mathbb{P}_\varepsilon^e \{ \mathcal{H}_\varepsilon(\alpha_{x_i}, a) \}.
\]
(4.24)
By Lemma 4.3,
\[
\limsup_{\varepsilon \to 0} \varepsilon \log \mathbb{P}_\varepsilon^e \{ \mathcal{H}_\varepsilon(\alpha_{x_i}, a) \} \leq -a, \quad \text{for each } i.
\]
(4.25)
Consequently, by (4.24),
\[
\limsup_{\varepsilon \to 0} \varepsilon \log \mathbb{P}_\varepsilon^e(\mathfrak{A}) \leq -a.
\]
(4.26)
The desired upper bound is then obtained by letting \(a \downarrow \inf_{x \in \text{cl} \mathfrak{A}} \Gamma_\varepsilon^*(x)\).

**Step 2:** The upper bound can be extended to the case where \(\mathfrak{A}\) and \(\mathcal{C}\) are possibly unbounded.

**Proof.** Let \(a\) be a finite constant such that \(a \leq \inf_{x \in \text{cl} \mathfrak{A}} \Gamma_\varepsilon^*(x)\). For \(R, K < \infty\), define:
\[
\mathfrak{A}_R = \mathfrak{A} \cap \{ (x_u, x_v) : \|x_u\| \leq R, \|x_u + x_v\| \leq R \}
\]
and
\[
\mathcal{C}_K = \mathcal{C} \cap ([0, K] \times [0, K]).
\]
Since \(\mathfrak{A}_R\) and \(\mathcal{C}_K\) are bounded, it follows by Step 1 that
\[
\limsup_{\varepsilon \to 0} \varepsilon \log \mathbb{P}_\varepsilon^e(\mathfrak{A}_R) \leq - \inf_{x \in \text{cl} \mathfrak{A}_R} \Gamma_\varepsilon^*(x) \leq - \inf_{x \in \text{cl} \mathfrak{A}_R} \Gamma_\varepsilon^*(x) \leq -a
\]
(4.27)
for any \( R, K < \infty \). [The second inequality holds because \( \mathcal{C}_K \subset \mathcal{C} \implies \Gamma_{\epsilon_K} \leq \Gamma_{\epsilon} \), hence \( \Gamma_{\epsilon_K}^* \geq \Gamma_{\epsilon}^* \).] We need to show that the bounded sets \( \mathfrak{A}_R \) and \( \mathcal{C}_K \) on the left of (4.27) may be replaced with the possibly unbounded sets \( \mathfrak{A} \) and \( \mathcal{C} \).

For this purpose, observe: \( Z_{m,n}^\epsilon \in \mathfrak{A} \cap \mathfrak{A}_R^\epsilon \iff \)

\[
(Y_m^\epsilon, Y_n^\epsilon - Y_m^\epsilon) \in \{(x_u, x_v) : (x_u, x_v) \in \mathfrak{A}, \|x_u\| > R \text{ or } \|x_u + x_v\| > R\}
\]

\[
\iff (Y_m^\epsilon, Y_n^\epsilon) \in \{(x_u, x_u + x_v) : (x_u, x_v) \in \mathfrak{A}, \|x_u\| > R \text{ or } \|x_u + x_v\| > R\}.
\]

By the definition of \( \text{proj}(\mathfrak{A}) \) it follows that

\[
Z_{m,n}^\epsilon \in \mathfrak{A} \cap \mathfrak{A}_R^\epsilon \implies Y_i^\epsilon \in \text{proj}(\mathfrak{A}) \cap B_{0,R}^\epsilon, \text{ either } i = m \text{ or } i = n \quad (4.28)
\]

[where \( B_{0,R} \) is a ball of radius \( R \) about the origin]. Hence the event \( \{Z_{m,n}^\epsilon \in (\mathfrak{A} \cap \mathfrak{A}_R^\epsilon), \ (m, n) \in \mathcal{C}_K/\epsilon\} \) is contained in the event \( \{Y_i^\epsilon \in \text{proj}(\mathfrak{A}) \cap B_{0,R}^\epsilon, \ i \in [0,K/\epsilon]\} \). The evaluation of the probability of this last event may then be handled by applying equation (4.14) of Collamore (1996a). Namely, since \( a < \infty \) and \( \text{proj}(\mathfrak{A}) \) satisfies (H2):

\[
\limsup_{\epsilon \to 0} \epsilon \log P \{Y_i^\epsilon \in \text{proj}(\mathfrak{A}) \cap B_{0,R}^\epsilon, \ i \in [0,K/\epsilon]\} \leq -a,
\]

sufficiently large \( R \). Consequently,

\[
\limsup_{\epsilon \to 0} \epsilon \log P_{\epsilon, \mathfrak{A}}^\epsilon (\mathfrak{A} \cap \mathfrak{A}_R^\epsilon) \leq -a,
\]

sufficiently large \( R \). Finally, observe that the event \( \{Z_{m,n}^\epsilon \in \mathfrak{A}, \ (m, n) \in \mathcal{C}_K/\epsilon\} \) is the union of the events \( \{Z_{m,n}^\epsilon \in \mathfrak{A}_R, \ (m, n) \in \mathcal{C}_K/\epsilon\} \) and \( \{Z_{m,n}^\epsilon \in \mathfrak{A} \cap \mathfrak{A}_R^\epsilon, \ (m, n) \in \mathcal{C}_K/\epsilon\} \). Therefore \( P_{\epsilon, \mathfrak{A}}^\epsilon (\mathfrak{A}) \leq P_{\epsilon, \mathfrak{A}_R}^\epsilon (\mathfrak{A} \cap \mathfrak{A}_R^\epsilon) + P_{\epsilon, \mathfrak{A}}^\epsilon (\mathfrak{A} \cap \mathfrak{A}_R^\epsilon) \). It follows by (4.27) and (4.30) that

\[
\limsup_{\epsilon \to 0} \epsilon \log P_{\epsilon, \mathfrak{A}}^\epsilon (\mathfrak{A}) \leq -a. \quad (4.31)
\]

It remains to show that \( \mathcal{C}_K \) may likewise be extended to \( \mathcal{C} \). By an argument similar to the one given in (4.28), \( Z_{m,n}^\epsilon \in \mathfrak{A} \implies \{Y_m^\epsilon, Y_n^\epsilon \} \in \text{proj}(\mathfrak{A}) \). Hence \( P_{\epsilon, \mathcal{C}_K}^\epsilon (\mathfrak{A}) \equiv P \{Z_{m,n}^\epsilon \in \mathfrak{A}, \ (m, n) \in \epsilon^{-1}(\mathcal{C} \cap \mathcal{C}_K^\epsilon)\} \) is bounded above by \( P \{Y_i^\epsilon \in \text{proj}(\mathfrak{A}), \ i \in [K/\epsilon, \infty]\} \). The evaluation of this last probability may be handled by applying equation (4.7) of Collamore (1996a). Namely, since \( a < \infty \) and \( \text{proj}(\mathfrak{A}) \) satisfies (H2):

\[
\limsup_{\epsilon \to 0} \epsilon \log P \{Y_i^\epsilon \in \text{proj}(\mathfrak{A}), \ i \in [K/\epsilon, \infty]\} \leq -a,
\]

sufficiently large \( K \). Hence

\[
\limsup_{\epsilon \to 0} \epsilon \log P_{\epsilon, \mathcal{C}_K}^\epsilon (\mathfrak{A}) \leq -a, \quad (4.33)
\]

sufficiently large \( K \). Since \( P_{\epsilon, \mathfrak{A}}^\epsilon (\mathfrak{A}) \leq P_{\epsilon, \mathcal{C}_K}^\epsilon (\mathfrak{A}) + P_{\epsilon, \mathcal{C}_K}^\epsilon (\mathfrak{A}) \), it follows by (4.31) and (4.33) that

\[
\limsup_{\epsilon \to 0} \epsilon \log P_{\epsilon}^\epsilon (\mathfrak{A}) \leq -a. \quad (4.34)
\]
Finally, the desired upper bound is obtained by letting $a \uparrow \inf_{x \in \mathcal{A}} \Gamma_\epsilon^x(x)$. □

Lower Bound. Fix $(\tau_u, \tau_v) \in \mathbb{R}^{2d}$ as follows: for each $\epsilon > 0$ let

$$\tilde{Z}_\epsilon = Z_{m_\epsilon, n_\epsilon}, \text{ where } m_\epsilon = \lfloor \tau_u / \epsilon \rfloor \text{ and } n_\epsilon = \lfloor \tau_v / \epsilon \rfloor,$$

and where $\lfloor x \rfloor$ denotes the greatest integer $\leq x$. The sequence $\{\tilde{Z}_\epsilon\}_{\epsilon > 0}$ has been constructed from elements of the original sequence, $\{Z_{m,n}\}_{m,n \in \mathbb{Z}_+}$. Its generating function is

$$\tilde{\Lambda}(\alpha) = \lim_{\epsilon \to 0} \epsilon \log \mathbb{E} \left[ \exp \{ \langle \alpha, \tilde{Z}_\epsilon \rangle \} \right] = \tau_v \lim_{\epsilon \to 0} \frac{1}{\tau_v / \epsilon} \log \mathbb{E} \left[ \exp \{ \langle \alpha, Z_{\lfloor \tau_u / \epsilon \rfloor, \lfloor \tau_v / \epsilon \rfloor} \rangle \} \right].$$

(4.35)

The limit on the right can be simplified by applying (H1). Since $\lfloor \tau_u / \epsilon \rfloor \to \infty$ and $\lfloor \tau_u / \epsilon \rfloor / \lfloor \tau_v / \epsilon \rfloor \to \tau_u / \tau_v$ as $\epsilon \to 0$, the right side of (4.35) can be identified as $\tau_v \Lambda_{\epsilon \tau_v}(\alpha)$. Hence, by (H1) and (4.35),

$$\tilde{\Lambda}(\alpha) = \tau_v \left[ \frac{\tau_u}{\tau_v} \Lambda(\alpha_u) + \left( 1 - \frac{\tau_u}{\tau_v} \right) \Lambda(\alpha_v) \right], \text{ where } \alpha = (\alpha_u, \alpha_v).$$

(4.36)

By (H0) and the Gärtner-Ellis theorem [Dembo and Zeitouni (1993), Theorem 2.3.6 (c)], it follows that the probability law of $\epsilon \tilde{Z}_\epsilon$ satisfies the large deviation principle with rate function

$$\hat{\Lambda}^*(x_u, x_v) = \sup_{\alpha_u, \alpha_v \in \mathbb{R}^d} \left[ \langle \alpha_u, x_u \rangle + \langle \alpha_v, x_v \rangle - \tau_u \Lambda(\alpha_u) - (\tau_v - \tau_u) \Lambda(\alpha_v) \right]$$

$$\begin{align*}
&= \tau_u \sup_{\alpha \in \mathbb{R}^d} \left[ \langle \alpha, \frac{x_u}{\tau_u} \rangle - \Lambda(\alpha) \right] + (\tau_v - \tau_u) \sup_{\alpha \in \mathbb{R}^d} \left[ \langle \alpha, \frac{x_v}{\tau_v - \tau_u} \rangle - \Lambda(\alpha) \right] \\
&= \tau_u \Lambda^* \left( \frac{x_u}{\tau_u} \right) + (\tau_v - \tau_u) \Lambda^* \left( \frac{x_v}{\tau_v - \tau_u} \right).
\end{align*}$$

(4.37)

Next observe

$$\mathbb{P}_\epsilon^x(\mathcal{A}) = \mathbb{P} \left\{ Z_{m,n} \in \mathcal{A}, (m,n) \in \mathcal{C}/\epsilon \right\} \geq \mathbb{P} \{ \tilde{Z}_\epsilon \in \mathcal{A} \},$$

(4.38)

where by definition $\tilde{Z}_\epsilon = Z_{m_\epsilon, n_\epsilon}, m_\epsilon = \lfloor \tau_u / \epsilon \rfloor, n_\epsilon = \lfloor \tau_v / \epsilon \rfloor$, and where $\epsilon$ is sufficiently small so that the operation $\lfloor \cdot \rfloor$ does not cause $(m_\epsilon, n_\epsilon)$ to jump outside of the interval $\mathcal{C}/\epsilon \supset \{(\tau_u / \epsilon, \tau_v / \epsilon)\}$. Applying the large deviation lower bound to the right side of (4.38) yields

$$\liminf_{\epsilon \to 0} \epsilon \log \mathbb{P}_\epsilon^x(\mathcal{A}) \geq - \inf_{z \in \mathcal{A}} \tilde{\Lambda}^*(z) \geq - \tilde{\Lambda}^*(x), \text{ for any } x \in \mathcal{A}. \quad (4.39)$$

Hence by (4.37):

$$\liminf_{\epsilon \to 0} \epsilon \log \mathbb{P}_\epsilon^x(\mathcal{A}) \geq - \left[ \tau_u \Lambda^* \left( \frac{x_u}{\tau_u} \right) + (\tau_v - \tau_u) \Lambda^* \left( \frac{x_v}{\tau_v - \tau_u} \right) \right],$$

(4.40)
for any $x = (x_u, x_v) \in \text{int } \mathfrak{A}$. Taking the supremum in (4.40) over all $(\tau_u, \tau_v) \in \text{int } \mathfrak{C}$, then applying Theorem 3.1, and finally taking the supremum over all $x \in \text{int } \mathfrak{A} - \partial(\text{dom } \Gamma^*_C)$, we obtain:

$$
\liminf_{\epsilon \rightarrow 0} \epsilon \log P^\epsilon_{\mathfrak{C}}(\mathfrak{A}) \geq - \inf_{x \in \text{int } \mathfrak{A} - \partial(\text{dom } \Gamma^*_C)} \Gamma^*_C(x). \tag{4.41}
$$

As $\text{int } \mathfrak{A}$ is open and $\Gamma^*_C$ convex, the extension of the infimum in (4.41) to all elements of $\text{int } \mathfrak{A}$ can then be handled as in the discussion following equation (4.9) of Collamore (1996a). Thus the required lower bound follows from (4.41). \qed

**Remark 4.4.** In Theorem 4.2 it is assumed that $\mathfrak{C} \subset \{(\tau_u, \tau_v) : \tau_v \geq \tau_u \geq 0\}$. Now suppose $\mathfrak{C} \subset \{(\tau_u, \tau_v) : \tau_u \geq 0, \tau_v \geq 0\}$, and assume $(0, 0) \notin \text{cl } \mathfrak{C}$. Put

$$
\mathfrak{C}_+ = \mathfrak{C} \cap \{ (\tau_u, \tau_v) : \tau_v \geq \tau_u \} \text{ and } \mathfrak{C}_- = \mathfrak{C} \cap \{ (\tau_u, \tau_v) : \tau_v < \tau_u \}.
$$

Then by Theorem 4.2 we have

$$
\lim_{\epsilon \rightarrow 0} \epsilon \log P^\epsilon_{\mathfrak{C}_+}(\mathfrak{A}) \approx - \inf_{x \in \mathfrak{A}_+} \Gamma^*_C(x) \tag{4.42}
$$

and similarly

$$
\lim_{\epsilon \rightarrow 0} \epsilon \log P^\epsilon_{\mathfrak{C}_-}(\mathfrak{A}) \approx - \inf_{x \in \mathfrak{A}_-} \Gamma^*_C(x), \tag{4.43}
$$

where $\mathfrak{C}_- = \{ (\tau_v, \tau_u) : (\tau_u, \tau_v) \in \mathfrak{C}_+ \}$ and $\mathfrak{A} = \{ (x_u + x_v, -x_v) : (x_u, x_v) \in \mathfrak{A} \}$. If we extend the definition of $Z_{m,n}$ in the natural way to $\{(m, n) : n < m\}$, then

$$
Z_{m,n} \equiv (Y_m, Y_n - Y_m) \in \mathfrak{A} \iff (Y_n, Y_m - Y_n) \in \mathfrak{A} \iff Z_{n,m} \in \mathfrak{A},
$$

implying $P^\epsilon_{\mathfrak{C}_-}(\mathfrak{A}) = P^\epsilon_{\mathfrak{C}_+}(\mathfrak{A})$. Thus it follows by (4.42) and (4.43) that

$$
\lim_{\epsilon \rightarrow 0} \epsilon \log P^\epsilon_{\mathfrak{C}}(\mathfrak{A}) \approx - \min \left\{ \inf_{x \in \mathfrak{A}} \Gamma^*_C(x), \inf_{x \in \mathfrak{A}} \Gamma^*_C(x) \right\} \tag{4.44}
$$

[where “$\approx$” may be replaced by the usual upper and lower bounds].

**Proof of Theorem 4.1.** Suppose $C$ is bounded, and let $\mathfrak{C} = C \times D$, where $D$ is chosen such that $C \times D \subset \{ (\tau_u, \tau_v) : \tau_v \geq \tau_u \geq 0 \}$ and $(0, 0) \notin \text{cl } (C \times D)$. Let $\alpha = (\tilde{\alpha}, 0)$. Then an application of Lemma 4.3 yields:

$$
\limsup_{\epsilon \rightarrow 0} \epsilon \log P^\epsilon_C \{ \mathcal{H}_C(\tilde{\alpha}, a) \} \leq -a, \tag{4.45}
$$

where $\mathcal{H}_C(\tilde{\alpha}, a) = \{ x : \langle \tilde{\alpha}, x \rangle > (a + \mathcal{H}_C(\tilde{\alpha})) \}.$

Approximate $P^\epsilon_C(A)$ with $\sum_{i=1}^k P^\epsilon_C \{ \mathcal{H}_C(\alpha_x, a) \},$ in the sense of (4.24), and use (4.45) to determine an upper bound for $P^\epsilon_C(A)$.

The proof of Theorem 4.1 then follows Theorem 4.2, so we omit the details. \qed
5 Proof of Theorem 1

Upper Bound. First assume that $F \subset [0, \infty)$ is compact.
For all $\delta > 0$ and all $\tau \in [0, \infty)$, let

$$B_{\delta}(\tau) = \{ \zeta \in [0, \infty) : |\zeta - \tau| < \delta \} \quad \text{and} \quad B_{\delta}(F) = \bigcup_{\tau \in F} B_{\delta}(\tau).$$

To apply Theorem 4.1, note

$$P \{ T^\tau(A) \in B_{\delta}(\tau) \} \leq P_{B_{\delta}(\tau)}^p(A); \quad (5.1)$$
on the left we have the probability that $\{ Y^\tau_n \}$ first hits $A$ during the time interval $B_{\delta}(\tau)/\epsilon$ and on the right the probability that $\{ Y^\tau_n \}$ ever hits $A$ during that interval. Hence

$$\limsup_{\epsilon \to 0} \epsilon \log P \{ T^\tau(A) \in B_{\delta}(\tau) \} \leq - \inf_{x \in A, B_{\delta}(\tau)} \Gamma^+_A(x) = - \inf_{x \in cl \ B_{\delta}(\tau)} \tilde{T}_A(\tilde{\tau}) \quad \text{(5.2)}$$

by Theorem 4.1 and then Theorems 3.1 and 3.2. Next observe that $\{ B_{\delta}(\tau) \}_{\tau \in F}$ is an open cover for $F$; hence there exists a finite subcover; and by applying (5.2) to the elements of this subcover we obtain

$$\limsup_{\epsilon \to 0} \epsilon \log P \{ T^\tau(A) \in F \} \leq - \inf_{\tau \in cl \ B_{\delta}(F)} \tilde{T}_A(\tau). \quad (5.3)$$

It remains to show

$$\inf_{\tau \in cl \ B_{\delta}(F)} \tilde{T}_A(\tau) \uparrow \inf_{\tau \in F} \tilde{T}_A(\tau) \quad \text{as} \quad \delta \downarrow 0. \quad (5.4)$$

Assume false. Then for each $i \in \mathbb{Z}_+$ there exists $x_i \in cl A$ and $\tau_i \in B_{\delta}(F)$ such that

$$\lim_{i \to \infty} \tau_i \Lambda^*(\frac{x_i}{\tau_i}) < \inf_{\tau \in F} \tilde{T}_A(\tau). \quad (5.5)$$

Then $F$ is compact $\implies$ along a subsequence $\tau_i \to \tau_0 \in F$. Next we observe that similarly $x_i \to x_0 \in cl A$. For this purpose, note: $\tau_0 \Lambda^*(x_i/\tau_i) \geq \Gamma^*_{[0, \infty)}(x_i)$ [Theorem 3.1]. Since the restriction of $\Gamma^*_{[0, \infty)}$ to $cl A$ has compact level sets [by hypothesis (H2) and Remark 3.5 (i)], it follows that $\{ x_i \}$ is bounded. Hence along a subsequence $x_i \to x_0 \in cl A$. If $\tau_0 \neq 0$, then by the lower semicontinuity of $\Lambda^*$,

$$\tau_0 \Lambda^*(\frac{x_0}{\tau_0}) \leq \lim_{i \to \infty} \tau_i \Lambda^*(\frac{x_i}{\tau_i}) \quad \text{as} \quad i \to \infty. \quad (5.6)$$

This shows that (5.5) is impossible in this case. On the other hand, if $\tau_0 = 0$, then observe

$$\left( \frac{x_i}{\tau_i}, \Lambda^*(\frac{x_i}{\tau_i}) \right) \in \text{epi} \Lambda^*, \quad \text{for all} \ i, \quad (5.7)$$

where (epi $\Lambda^*$) is the epigraph of $\Lambda^*$. By Theorem 8.2 of Rockafellar (1970), it follows that

$$\left( x_0, \lim_{\tau_i \to 0} \tau_i \Lambda^*(\frac{x_i}{\tau_i}) \right) = \lim_{\tau_i \to 0} \tau_i \left( \frac{x_i}{\tau_i}, \Lambda^*(\frac{x_i}{\tau_i}) \right) \in 0^+(\text{epi} \Lambda^*). \quad (5.8)$$

Hence, by definition of the recession function, the limit on the left of (5.5) is $\geq (0^+ \Lambda^*)(x_0) \geq \tilde{T}_A(0)$, and so (5.5) is once again impossible.
By (5.3) and (5.4) we conclude that the upper bound holds for all compact sets $F \subset [0, \infty)$. Finally, the extension to closed but unbounded sets may be handled by applying equation (4.7) of Collamore (1996a).

**Lower Bound.** First assume that $G$ is an interval which is open in $[0, \infty)$. Thus $G = (\tau_1, \tau_2)$, where $0 \leq \tau_1 < \tau_2 \leq \infty$, or $G = [\tau_1, \tau_2)$, where $\tau_1 = 0$ and $0 < \tau_2 \leq \infty$. Let $[\zeta_1, \zeta_2] \subset (\tau_1, \tau_2)$, and let $\mathcal{C} = [0, \tau_1] \times (\zeta_1, \zeta_2)$.

Let
\[
\mathcal{D}_C = \text{dom } \Gamma^*_C, \quad \text{for all intervals } C \subset [0, \infty);
\]
\[
\mathfrak{S}_\delta = \{ y : \| y - x \| < \delta \text{ for some } x \in \partial \mathcal{D}_{\{\zeta_1, \zeta_2\}} \}, \quad \text{for all } \delta > 0;
\]
\[
\mathfrak{A}_\delta = \text{int } (A - \mathfrak{S}_\delta), \quad \text{for all } \delta > 0;
\]
\[
\mathfrak{M}_\delta = \{ (x_u, x_v) : x_u \in A, x_u + x_v \in \mathfrak{A}_\delta \}, \quad \text{for all } \delta > 0;
\]
\[
\mathfrak{M}_\delta \cap \mathfrak{S}_\delta = \{ x_0 \in \text{cl } \mathcal{E} : \Gamma^*_A(x_0) = \inf_{x \in \mathcal{E}} \Gamma^*_{\{\zeta_1, \zeta_2\}}(x) \}, \quad \text{for all sets } \mathcal{E} \subset \mathbb{R}^d.
\]

Note that the open set $A_\delta \uparrow [\text{int } A - \partial \mathcal{D}_{\{\zeta_1, \zeta_2\}}]$ as $\delta \downarrow 0$.

Consider:

(i) $\mathbb{P}^e_{\{\zeta_1, \zeta_2\}}(A_\delta) = \mathbb{P}\{ Y^e_n \in A_\delta, \ n \in \epsilon^{-1}(\zeta_1, \zeta_2) \}$,

(ii) $\mathbb{P}^e_{\mathcal{E}}(A_\delta) = \mathbb{P}\{ (Y^e_n, Y^e_m) \in A \times A_\delta, \ m \in \epsilon^{-1}[0, \tau_1] \text{ and } n \in \epsilon^{-1}(\zeta_1, \zeta_2) \}$.

The quantity given in (i) is the probability that $\{ Y^e_n \}_{n \in \mathbb{Z}_+}$ hits $A_\delta$ during the interval $\epsilon^{-1}(\zeta_1, \zeta_2)$. The quantity given in (ii) is the probability that $\{ Y^e_n \}_{n \in \mathbb{Z}_+}$ hits $A$ during the interval $\epsilon^{-1}[0, \tau_1]$ and then $A_\delta$ during the interval $\epsilon^{-1}(\zeta_1, \zeta_2)$. If we subtract (ii) from (i), we obtain the probability that $\{ Y^e_n \}_{n \in \mathbb{Z}_+}$ hits $A_\delta$ during the interval $\epsilon^{-1}(\zeta_1, \zeta_2)$ but does not hit $A$ during the prior interval $\epsilon^{-1}[0, \tau_1]$. Since $A_\delta \subset A$, this is a lower bound for the probability that $\{ Y^e_n \}$ first hits $A$ during the interval $\epsilon^{-1}G \supset \epsilon^{-1}(\zeta_1, \zeta_2)$. In other words,

\[
\mathbb{P}\{ T^e(A) \in G \} \geq \mathbb{P}^e_{\{\zeta_1, \zeta_2\}}(A_\delta) - \mathbb{P}^e_{\mathcal{E}}(A_\delta).
\]

As $\epsilon \to 0$, the exponential rate of decay of $\mathbb{P}^e_{\{\zeta_1, \zeta_2\}}(A_\delta)$ is $\leq \left\{ \epsilon^{-1} \inf_{x \in A_\delta} \Gamma^*_{\{\zeta_1, \zeta_2\}}(x) \right\}$, by Theorem 4.1 (ii), while the exponential rate of decay of $\mathbb{P}^e_{\mathcal{E}}(A_\delta)$ is $\geq \left\{ \epsilon^{-1} \inf_{x \in \text{cl } \mathfrak{M}_\delta} \Gamma^*_{\{\zeta_1, \zeta_2\}}(x) \right\}$, by Theorem 4.2 (i). The next lemma shows that this decay is actually dominated by the first term on the right of (5.9).

**Lemma 5.1.** Assume $\inf_{x \in A_\delta} \Gamma^*_{\{\zeta_1, \zeta_2\}}(x)$ is finite for some $\delta > 0$. Then there exists a positive real number $\delta_0$ such that

\[
\inf_{x \in \text{cl } \mathfrak{M}_\delta} \Gamma^*_{\mathcal{E}}(x) > \inf_{x \in A_\delta} \Gamma^*_{\{\zeta_1, \zeta_2\}}(x), \quad \text{for all } 0 < \delta \leq \delta_0.
\]

**Proof of Lemma 5.1.** Since $A_\delta$ increases in size as $\delta \to 0$, the assumption of the lemma implies

\[
A_\delta \cap \text{dom } \Gamma^*_{\{\zeta_1, \zeta_2\}} \neq \emptyset, \quad \text{for all } 0 < \delta \leq \delta_0.
\]
Since the elements of the collection \( \{A_\delta\}_{\delta > 0} \) have been constructed to be disjoint from \( \partial \mathcal{D}_{(\zeta_1, \zeta_2)} \) [the relative boundary of the domain of \( \Gamma^*_{(\zeta_1, \zeta_2)} \)], it follows by (5.11) that
\[
A_\delta \cap \text{ri} \mathcal{D}_{(\zeta_1, \zeta_2)} \neq \emptyset, \quad \text{for all } 0 < \delta \leq \delta.
\] (5.12)

Hence the conditions of Theorem 3.4 (i), (ii) are satisfied with \( f = \Gamma^*_{(\zeta_1, \zeta_2)}, \mathcal{E} = A_\delta \), and \( 0 < \delta \leq \delta \). From now on, we will assume that \( \delta \) has been chosen in the interval \((0, \delta]\), so that this is true.

Also, let \( (x_{0u}, x_{0v}) \in \mathbb{R}^d \times \mathbb{R}^d \) be an element obtained by Theorem 3.4 (i) with \( f = \Gamma^*_\varepsilon \) and \( \mathcal{E} = A_\delta \).

We begin by relating \( \Gamma^*_\varepsilon \) to \( \Gamma^*_{(\zeta_1, \zeta_2)} \).

**Step 1:** (i) For any \( \alpha \in \mathbb{R}^d \), \( \Gamma^*_\varepsilon(\alpha, \alpha) = \Gamma^*_{(\zeta_1, \zeta_2)}(\alpha) \).

(ii) For any \( x_u, x_v \in \mathbb{R}^d \), \( \Gamma^*_\varepsilon(x_u, x_v) \geq \Gamma^*_{(\zeta_1, \zeta_2)}(x_u + x_v) \).

**Proof.** By definition
\[
\Gamma^*_\varepsilon(\alpha, \alpha) = \sup_{(\tau_u, \tau_v) \in \mathcal{E}} \left\{ \tau_u \Lambda(\alpha) + (\tau_v - \tau_u) \Lambda(\alpha) \right\} = \sup_{\tau_v \in (\zeta_1, \zeta_2)} \tau_v \Lambda(\alpha) = \Gamma^*_{(\zeta_1, \zeta_2)}(\alpha),
\]
hence
\[
\Gamma^*_\varepsilon(x_u, x_v) \geq \sup_{(\alpha, \alpha) \in \mathbb{R}^{2d}} \left\{ \langle \alpha, x_u \rangle + \langle \alpha, x_v \rangle - \Gamma^*_\varepsilon(\alpha, \alpha) \right\} = \Gamma^*_{(\zeta_1, \zeta_2)}(x_u + x_v). \quad \Box
\]

**Step 2:** \( x_{0u} + x_{0v} \notin \mathbb{M}_{A_\delta} \implies \inf_{x \in \text{cl} A_\delta} \Gamma^*_\varepsilon(x) > \inf_{x \in A_\delta} \Gamma^*_{(\zeta_1, \zeta_2)}(x) \).

**Proof.** Note \( (x_{0u}, x_{0v}) \in \text{cl} A_\delta = \text{cl} \{ (x_u, x_v) : (x_u, x_u + x_v) \in A \times A_\delta \} \implies x_{0u} + x_{0v} \in \text{cl} A_\delta \). Hence, if \( x_{0u} + x_{0v} \notin \mathbb{M}_{A_\delta} \), then
\[
\Gamma^*_{(\zeta_1, \zeta_2)}(x_{0u} + x_{0v}) > \inf_{x \in A_\delta} \Gamma^*_{(\zeta_1, \zeta_2)}(x). \quad (5.13)
\]
Consequently \( \Gamma^*_\varepsilon(x_{0u}, x_{0v}) > \inf_{x \in A_\delta} \Gamma^*_{(\zeta_1, \zeta_2)}(x) \) [Step 1 (ii)]. By the choice of \( (x_{0u}, x_{0v}) \) it follows that
\[
\inf_{x \in \text{cl} A_\delta} \Gamma^*_\varepsilon(x) > \inf_{x \in A_\delta} \Gamma^*_{(\zeta_1, \zeta_2)}(x). \quad \Box
\]

This establishes the lemma for the case \( x_{0u} + x_{0v} \notin \mathbb{M}_{A_\delta} \) and we turn next to the general case. The proof of the lemma for the general case is reliant upon the following.

**Step 3:** Suppose \( x_{0u} + x_{0v} \in \mathbb{M}_{A_\delta} \). Then
\[
\inf_{x \in \text{cl} A_\delta} \Gamma^*_\varepsilon(x) \leq \inf_{x \in A_\delta} \Gamma^*_{(\zeta_1, \zeta_2)}(x) \implies x_{0u} = c x_{0v} \quad \text{for some constant } c \in \left(0, \frac{\tau_1}{\zeta_1 - \tau_1}\right].
\]

**Proof.** Let \( x_0 = x_{0u} + x_{0v} \). Then \( x_0 \in \mathbb{M}_{A_\delta} \), i.e. \( x_0 \) satisfies Theorem 3.4 (i) with \( f = \Gamma^*_{(\zeta_1, \zeta_2)} \) and \( \mathcal{E} = A_\delta \). Let \( \alpha_0 \) be an element which satisfies Theorem 3.4 (ii) with
\[ f = \Gamma_{(\zeta_1, \zeta_2)} \] and \( \mathcal{E} = A_\delta \). Since \( x_0, \alpha_0 \) satisfy Theorem 3.4 (i), (ii), it follows by Theorem 23.5 of Rockafellar (1970) that

\[
\inf_{x \in A_\delta} \Gamma^*_{(\zeta_1, \zeta_2)}(x) = \Gamma^*_{(\zeta_1, \zeta_2)}(x_0) = \{ \langle \alpha_0, x_0 \rangle - \Gamma_{(\zeta_1, \zeta_2)}(\alpha_0) \}. \tag{5.14}
\]

Therefore, if we assume

\[
\inf_{x \in \text{cl } A_\delta} \Gamma^*_\mathcal{E}(x) \leq \inf_{x \in A_\delta} \Gamma^*_{(\zeta_1, \zeta_2)}(x),
\]

then it follows that

\[
\inf_{x \in \text{cl } A_\delta} \Gamma^*_\mathcal{E}(x) \leq \{ \langle \alpha_0, x_0 \rangle - \Gamma_{(\zeta_1, \zeta_2)}(\alpha_0) \}. \tag{5.15}
\]

The left side of (5.15) can be identified as \( \Gamma^*_\mathcal{E}(x_{0,u}, x_{0,v}) \), since \((x_{0,u}, x_{0,v})\) was chosen as an element at which \( \Gamma^*_\mathcal{E} \) attains its infimum over \( \text{cl } A_\delta \). The right side of (5.15) can be identified as \( \{ \langle \alpha_0, x_{0,u} \rangle + \langle \alpha_0, x_{0,v} \rangle - \Gamma_{(\zeta_1, \zeta_2)}(\alpha_0) \} \), since by definition \( x_0 = x_{0,u} + x_{0,v} \), and by Step 1 (i) we have \( \Gamma_{(\zeta_1, \zeta_2)}(\alpha_0) = \Gamma_{(\zeta_1, \zeta_2)}(\alpha_0) \). Hence (5.15) gives

\[
\Gamma^*_\mathcal{E}(x_{0,u}, x_{0,v}) \leq \{ \langle \alpha_0, x_{0,u} \rangle + \langle \alpha_0, x_{0,v} \rangle - \Gamma_{(\zeta_1, \zeta_2)}(\alpha_0) \}, \tag{5.16}
\]

implying \( (x_{0,u}, x_{0,v}) \in \partial \Gamma_{(\zeta_1, \zeta_2)}(\alpha_0) \) [Rockafellar (1970), Theorem 23.5]. By Theorem 3.6 we then obtain

\[
(x_{0,u}, x_{0,v}) = \nabla \Gamma_{(\zeta_1, \zeta_2)}(\alpha_0, \alpha_0) = (\tau_u \nabla \Lambda(\alpha_0), (\tau_v - \tau_u) \nabla \Lambda(\alpha_0)), \tag{5.17}
\]

for some \( (\tau_u, \tau_v) \in \text{cl } \mathcal{C} = [0, \tau_1] \times [\zeta_1, \zeta_2] \). Finally note \( (x_{0,u}, x_{0,v}) \in \text{cl } A_\delta \implies x_{0,u} \in \text{cl } A \); then \( (H2) \implies 0 \notin \text{cl } A \implies x_{0,u} \neq 0 \). As a result, by (5.17) we obtain \( x_{0,u} = c x_{0,v} \), where \( c = \tau_u/(\tau_v - \tau_u) \in (0, \tau_1/(\zeta_1 - \tau_1)] \). \( \square \)

We are now prepared to establish the lemma.

**Step 4:** If \( \delta \leq \text{some } \delta_0 \), then \( \inf_{x \in \text{cl } A_\delta} \Gamma^*_\mathcal{E}(x) > \inf_{x \in A_\delta} \Gamma^*_{(\zeta_1, \zeta_2)}(x) \).

**Proof.** Assume false. Then

\[
\inf_{x \in \text{cl } A_{\delta_i}} \Gamma^*_\mathcal{E}(x) \leq \inf_{x \in A_{\delta_i}} \Gamma^*_{(\zeta_1, \zeta_2)}(x) \tag{5.18}
\]

for a sequence \( \{ \delta_i \}_{i \in \mathbb{Z}_+} \) where \( \delta_i \to 0 \) as \( i \to \infty \). Along this sequence, it follows by Step 2 that

\[
x^{(i)}_0 \equiv x^{(i)}_{0,u} + x^{(i)}_{0,v} \in \mathcal{M}_{A_{\delta_i}}. \tag{5.19}
\]

Hence it follows by Step 3 that

\[
x^{(i)}_{0,u} = c^{(i)} x^{(i)}_{0,v}, \quad \text{some constant } c^{(i)} \in \left(0, \frac{\tau_1}{\zeta_1 - \tau_1}\right). \tag{5.20}
\]

By combining (5.19) and (5.20) we obtain:

\[
x^{(i)}_0 = K^{(i)} x^{(i)}_{0,u}, \tag{5.21}
\]

27
where \( K^{(i)} \equiv \left( 1 + \frac{1}{\epsilon^{(i)}} \right) \in \left( \frac{1}{\tau_1}, \infty \right) \). We study the limiting behavior of (5.21) as \( i \to \infty \).

First consider \( x_0^{(i)} \) as \( i \to \infty \). Since \( x_0^{(i)} \in \mathfrak{M}_{A_{\delta_i}} \),

\[
\Gamma_{G^{(1)},G^{(2)}}^*(x_0^{(i)}) = \inf_{x \in A_{\delta_i}} \Gamma_{G^{(1)},G^{(2)}}^*(x) \downarrow \inf_{x \in \text{int} A - \partial D_{G^{(1)},G^{(2)}}} \Gamma_{G^{(1)},G^{(2)}}^*(x) \text{ as } i \uparrow \infty.
\] (5.22)

Since \( \Gamma_{G^{(1)},G^{(2)}}^* \) has compact level sets on \( \partial A \) [as in Remark 3.5 (i)], it follows that the sequence \( \{x_0^{(i)}\} \) is bounded. Hence \( x_0^{(i)} \in \partial A_{\delta_i} \) converges [possibly after passing to a subsequence] to some point \( x_0 \in \partial A \). Furthermore, by (5.22) and the lower semicontinuity of \( \Gamma_{G^{(1)},G^{(2)}}^* \),

\[
\Gamma_{G^{(1)},G^{(2)}}^*(x_0) = \inf_{x \in \text{int} A - \partial D_{G^{(1)},G^{(2)}}} \Gamma_{G^{(1)},G^{(2)}}^*(x).
\] (5.23)

The infimum on the right of (5.23) can be extended to all elements of \( (\text{int} A) \) as in the discussion following equation (4.9) of Collamore (1996a). Hence \( x_0 \in \mathfrak{M}_{\text{int} A} \). We conclude that \( x_0 \) is actually a boundary point of \( A \) [Remark 3.5 (ii)].

Next consider \( x_0^{(i)} \) as \( i \to \infty \). Since \( \{x_0^{(i)}\} \) is bounded and \( K^{(i)} \geq \frac{c_0}{\tau_1} > 1 \), it follows by (5.21) that \( \{x_0^{(i)}\} \) is likewise bounded. Hence \( x_0^{(i)} \in \partial A \) converges [possibly after passing to a subsequence] to some point \( x_{0,u} \in \partial A \).

Going back to (5.21) and letting \( i \to \infty \), we now obtain

\[
x_0 = Kx_{0,u}, \quad \text{where } x_0 \in \partial A, \quad x_{0,u} \in \partial A, \quad \text{and } K \geq \frac{c_0}{\tau_1} > 1.
\] (5.24)

Then \( x_{0,u} \in \partial A \implies \lambda x_{0,u} \in \partial A \) for some \( 0 < \lambda \leq 1 \), and if \( A \) is a semi-cone, this implies \( x_0 = (K/\lambda)x_{0,u} \) is an interior point of \( A \). We have reached a contradiction. \( \Box \)

By Lemma 5.1 and the discussion following (5.9),

\[
\lim_{\epsilon \to 0} \epsilon \log P \left\{ T^\epsilon(A) \in G \right\} \geq - \inf_{x \in A_{\delta}} \Gamma_{G^{(1)},G^{(2)}}^*(x), \quad \text{for all } \delta \leq \text{some } \delta_0.
\] (5.25)

To obtain the required lower bound, let \( \delta \downarrow 0 \) and then let \( (\zeta_1, \zeta_2) \uparrow G \). As \( \delta \downarrow 0 \), we have by definition that \( A_{\delta} \uparrow \left[ \text{int} A - \partial D_{G^{(1)},G^{(2)}} \right] \). As \( (\zeta_1, \zeta_2) \uparrow G \), we have by Theorem 3.1 that \( \text{ri} D_{(G^{(1)},G^{(2)})} \uparrow \text{ri} D_G \). Hence by (5.25) we obtain

\[
\liminf_{\epsilon \to 0} \epsilon \log P \left\{ T^\epsilon(A) \in G \right\} \geq - \inf_{x \in \text{int} A - \partial D_G} \Gamma_{G}^*(x).
\] (5.26)

The infimum on the right of (5.26) can be extended to all elements of \( (\text{int} A) \) as in the discussion following equation (4.9) of Collamore (1996a). Thus (5.26) implies

\[
\liminf_{\epsilon \to 0} \epsilon \log P \left\{ T^\epsilon(A) \in G \right\} \geq - \inf_{x \in \text{int} A} \Gamma_{G}^*(x) \geq - \inf_{x \in G} \mathcal{L}_A(\tau),
\] (5.27)

the last step having been obtained by Theorems 3.1 and 3.2. This establishes the lower bound for open intervals \( G \subset [0, \infty) \). Since any open subset of \( [0, \infty) \) can be written as a countable union of such open intervals, the extension to general open sets follows immediately from (5.27). \( \Box \)
6 Proofs of Theorems 2 and 3

First we turn to the proof of Theorem 2, namely, to the identification of the most likely normalized first passage time.

To distinguish the most likely first passage time, we need to determine where \( I_A(\tau) \) is minimized as a function of \( \tau \) for convex sets \( A \subset \mathbb{R}^d \). Since

\[
\inf_{\tau \in C} I_A(\tau) = \inf_{x \in A} \Gamma^*_C(x) \quad \text{for all closed convex } C \subset [0, \infty)
\]

[Remark 3.3], we may determine this by finding which intervals minimize the quantity on the right of (6.1), that is, which \( C \subset [0, \infty) \) satisfy

\[
\inf_{x \in A} \Gamma_C(x) = \min_{C \subset [0, \infty)} \left\{ \inf_{x \in A} \Gamma^*_C(x) \right\}.
\]

The minimum on the right of (6.2) is actually \( \inf_{x \in A} \Gamma^*_C(x) = \Gamma^*_C(x_0) \), for a unique point \( x_0 \in \text{cl } A \) [Theorems 3.4 and 3.7], and the infimum on the left can only achieve this value at \( x_0 \) [since at another \( x \in \text{cl } A \) we have \( \Gamma_C(x) > \Gamma_C(x_0) \)]. Thus it is enough to show (6.2) locally at \( x_0 \), and this is the subject of the next theorem.

**Theorem 6.1.** Suppose \( A \) is a convex set satisfying (H2), \( A \cap \text{ri cone (dom } \Lambda^*) \neq \emptyset \), and \( \Lambda \) is differentiable on its domain. Let \( x_0 \) and \( a_0 \) be given as in Theorem 3.4 when \( f = \Gamma^*_{[0, \infty)} \) and \( E = A \), and let \( \rho \) be the constant given in Theorem 3.7 (ii). Then for any convex \( C \subset [0, \infty) \),

\[
\Gamma_C(x_0) = \min_{C \subset [0, \infty)} \Gamma^*_C(x_0) \iff \rho \in \text{cl } C.
\]

We remark that the minimum in (6.3) and in Step 1 below is over all convex \( \tilde{C} \) such that \( \text{int } \tilde{C} = (\tau_1, \tau_2) \), where \( 0 \leq \tau_1 < \tau_2 \leq \infty \).

**Proof of Theorem 6.1.** We first identify the minimum value of \( \Gamma_C(x_0) \) over \( C \subset [0, \infty) \). Then we show that this minimum value is attained \( \iff \rho \in \text{cl } C \).

**Step 1:** \( \min_{C \subset [0, \infty)} \Gamma^*_C(x_0) = \langle a_0, x_0 \rangle \).

**Proof.** Note \( \Gamma_C \leq \Gamma_{[0, \infty)} \) for \( C \subset [0, \infty) \), hence \( \Gamma^*_C \geq \Gamma^*_{[0, \infty)} \). Thus

\[
\min_{C \subset [0, \infty)} \Gamma^*_C(x_0) = \Gamma^*_{[0, \infty)}(x_0).
\]

Next observe that by definition \( \Gamma^*_{[0, \infty)}(x_0) = \sup_{\alpha \in \mathbb{R}^d} \{ \langle \alpha, x_0 \rangle - \mathbf{1}_{L_0}(\alpha) \} \), where \( \mathbf{1}_{L_0}(\cdot) \) is the indicator function on \( L_0 \Lambda \). Hence

\[
\Gamma^*_{[0, \infty)}(x_0) = \{ \langle \alpha, x_0 \rangle - \mathbf{1}_{L_0}(\alpha) \}_{\alpha = a_0} = \langle a_0, x_0 \rangle
\]

[Rockafellar (1970), Theorem 23.5, and Theorem 3.7 (i)].

In the remaining steps, we show that the minimum value obtained in Step 1 is achieved \( \iff \rho \in \text{cl } C \).
Step 2: If $\rho \in \text{cl } C$, then $\Gamma^*_C(x_0) = \langle \alpha_0, x_0 \rangle$.

Proof. Note $\rho \in \text{cl } C \implies \sup_{\tau \in C} \tau \Lambda(\cdot) \geq \rho \Lambda(\cdot)$. Hence

$$\Gamma^*_C(x_0) \equiv \sup_{a \in \mathbb{R}^d} \left\{ \langle \alpha, x_0 \rangle - \sup_{\tau \in C} \tau \Lambda(\alpha) \right\} \leq \sup_{a \in \mathbb{R}^d} \left\{ \langle \alpha, x_0 \rangle - \rho \Lambda(\alpha) \right\}. \quad (6.6)$$

Since $\nabla(\rho \Lambda)(\alpha_0) = \rho \nabla \Lambda(\alpha_0) = x_0$, it follows that

$$\Gamma^*_C(x_0) \leq \left\{ \langle \alpha, x_0 \rangle - \rho \Lambda(\alpha) \right\}_{\alpha = \alpha_0} = \langle \alpha_0, x_0 \rangle \quad (6.7)$$

[Rockafellar (1970), Theorem 23.5, and Theorem 3.7 (i)].

Step 3: If $\rho \notin \text{cl } C$, then $\Gamma^*_C(x_0) > \langle \alpha_0, x_0 \rangle$.

Proof. Since $C \subset \mathbb{R}$ is convex, we have $\text{int } C = (\tau_1, \tau_2)$, where $0 \leq \tau_1 < \tau_2 \leq \infty$.

First consider the case $\tau_1, \tau_2 > \rho$.

Assume to the contrary that

$$\Gamma^*_C(x_0) \equiv \sup_{a \in \mathbb{R}^d} \left\{ \langle \alpha, x_0 \rangle - \sup_{\tau \in C} \tau \Lambda(\alpha) \right\} = \langle \alpha_0, x_0 \rangle \quad (6.8)$$

and derive a contradiction.

Note: $\nabla(\rho \Lambda)(\alpha_0) = \rho \nabla \Lambda(\alpha_0) = x_0$. Hence

$$\sup_{a \in \mathbb{R}^d} \left\{ \langle \alpha, x_0 \rangle - \rho \Lambda(\alpha) \right\} = \left\{ \langle \alpha, x_0 \rangle - \rho \Lambda(\alpha) \right\}_{\alpha = \alpha_0} = \langle \alpha_0, x_0 \rangle \quad (6.9)$$

[Rockafellar (1970), Theorem 23.5, and Theorem 3.7 (i)]. Then, by (6.8) and (6.9),

$$\max_{\{\alpha: \Lambda(\alpha) \leq 0\}} \left\{ \sup_{\tau \in C} \langle \alpha, x_0 \rangle - \sup_{\tau \in C} \tau \Lambda(\alpha) \right\}, \sup_{\{\alpha: \Lambda(\alpha) > 0\}} \left\{ \langle \alpha, x_0 \rangle - \rho \Lambda(\alpha) \right\} \leq \langle \alpha_0, x_0 \rangle. \quad (6.10)$$

Next observe

$$\tau_1 \Lambda(\alpha) = \max_{i=1,2} \tau_i \Lambda(\alpha) = \sup_{\tau \in C} \tau \Lambda(\alpha) \quad \text{on } \{ \alpha: \Lambda(\alpha) \leq 0 \}, \quad (6.11)$$

and since $\tau_1 \geq \rho$,

$$\tau_1 \Lambda(\alpha) \geq \rho \Lambda(\alpha) \quad \text{on } \{ \alpha: \Lambda(\alpha) > 0 \}. \quad (6.12)$$

By (6.10), (6.11) and (6.12), it follows that

$$\sup_{a \in \mathbb{R}^d} \left\{ \langle \alpha, x_0 \rangle - \tau_1 \Lambda(\alpha) \right\} \leq \langle \alpha_0, x_0 \rangle. \quad (6.13)$$

Since $\left\{ \langle \alpha, x_0 \rangle - \tau_1 \Lambda(\alpha) \right\}_{\alpha = \alpha_0} = \langle \alpha_0, x_0 \rangle$ [Theorem 3.7 (i)], it then follows by (6.13) that

$$\sup_{a \in \mathbb{R}^d} \left\{ \langle \alpha, x_0 \rangle - \tau_1 \Lambda(\alpha) \right\} = \left\{ \langle \alpha, x_0 \rangle - \tau_1 \Lambda(\alpha) \right\}_{\alpha = \alpha_0}. \quad (6.14)$$
Hence \( x_0 = \nabla(\tau_1 A)(0) \) [Rockafellar (1970), Theorem 23.5], or \( \nabla A(0) = x_0/\tau_1 \). But \( \nabla A(0) = x_0/\rho \) and \( \tau_1, \tau_2 > \rho \). We have reached a contradiction.

If \( \tau_1, \tau_2 < \rho \), then it can be shown under (6.8) that

\[
\tau_2 A(\alpha) = \max_{i=1,2} \tau_i A(\alpha) \text{ on } \{ \alpha : A(\alpha) \geq 0 \}, \quad \tau_2 A(\alpha) \geq \rho A(\alpha) \text{ on } \{ \alpha : A(\alpha) < 0 \}, \quad (6.15)
\]

and a repetition of the above argument then gives \( \nabla A(0) = x_0/\tau_2 \), a contradiction.

This completes the proof of Step 3 and hence the theorem. \( \square \)

Next we apply Theorem 6.1 to show that the most likely normalized first passage time is \( T^*(A) \approx \rho \).

**Proof of Theorem 2.** If \( \{Y_n^*\}_{n \in \mathbb{Z}_+} \) first hits \( A \) at a time outside of the interval \( \epsilon^{-1}[\rho - \gamma, \rho + \gamma] \), then either \( \{Y_n^*\}_{n \in \mathbb{Z}_+} \) first hits \( A \) during the interval \( \epsilon^{-1}[0, \rho - \gamma] \) or during the interval \( \epsilon^{-1}(\rho + \gamma, \infty) \). Thus

\[
P \left\{ \left| T^*(A) - \rho \right| > \gamma \text{ and } T^*(A) < \infty \right\} = P \left\{ T^*(A) \in [0, \rho - \gamma) \right\} + P \left\{ T^*(A) \in (\rho + \gamma, \infty) \right\}. \quad (6.16)
\]

Then \( P \left\{ \left| T^*(A) - \rho \right| > \gamma \right| T^*(A) < \infty \} \) is obtained by dividing left and right hand sides by \( P \{ T^*(A) < \infty \} \). On the right side we have, for example,

\[
P \left\{ T^*(A) \in [0, \rho - \gamma) \right\} / P \{ T^*(A) < \infty \}
\]

and, by Theorem 1 and Remark 2.2,

\[
\limsup_{\epsilon \to 0} \epsilon \log \left( P \{ T^*(A) \in [0, \rho - \gamma) \} / P \{ T^*(A) < \infty \} \right) \leq - \inf_{\tau \in [0, \rho - \gamma)} T_A(\tau) + \inf_{\tau \in (0, \infty)} I_A(\tau) = - \inf_{x \in \partial A} \Gamma^*[0, \rho - \gamma)(x) + \inf_{x \in \partial A} \Gamma^*[0, \infty)(x). \quad (6.17)
\]

[The last step follows by Theorems 3.1 and 3.2. The last infimum has been extended from \( \text{int } A \) to \( \text{cl } A \) because \( A \) is assumed to be a convex open set intersecting \( \text{ri } (\text{dom } \Gamma^*[0, \infty)) \). By an analogous application of Theorem 1,

\[
\limsup_{\epsilon \to 0} \epsilon \log \left( P \{ T^*(A) \in (\rho + \gamma, \infty) \} / P \{ T^*(A) < \infty \} \right) \leq - \inf_{x \in \partial A} \Gamma^*_{(\rho + \gamma, \infty)}(x) + \inf_{x \in \partial A} \Gamma^*[0, \infty)(x). \quad (6.18)
\]

Thus, dividing left and right hand sides of (6.16) by \( P \{ T^*(A) < \infty \} \) and taking the limit as \( \epsilon \to 0 \), we obtain by (6.17) and (6.18):

\[
\limsup_{\epsilon \to 0} \epsilon \log P \left\{ \left| T^*(A) - \rho \right| > \gamma \right| T^*(A) < \infty \} \leq - \inf \left\{ \inf_{x \in \partial A} \Gamma^*[0, \rho - \gamma)(x), \inf_{x \in \partial A} \Gamma^*_{(\rho + \gamma, \infty)}(x) \right\} + \inf_{x \in \partial A} \Gamma^*[0, \infty)(x). \quad (6.19)
\]

**Assertion.** \( \min \left\{ \inf_{x \in \partial A} \Gamma^*[0, \rho - \gamma)(x), \inf_{x \in \partial A} \Gamma^*_{(\rho + \gamma, \infty)}(x) \right\} > \inf_{x \in \partial A} \Gamma^*[0, \infty)(x) \).
Proof. First we show
\[
\inf_{x \in \partial A} \Gamma^*(0,\rho_{-\gamma})(x) > \inf_{x \in \partial A} \Gamma^*(0,\infty)(x).
\] (6.20)

Let \( \bar{x}_0, x_0 \) be given as in Theorem 3.4 (i) when \( \mathcal{E} = \partial A \) and \( f = \Gamma^*(0,\rho_{-\gamma}), \Gamma^*(0,\infty) \), respectively.

If \( \bar{x}_0 \neq x_0 \), then \( \Gamma^*(0,\rho_{-\gamma})(\bar{x}_0) > \Gamma^*(0,\infty)(x_0) \), since \( x_0 \) is the unique element which minimizes \( \Gamma^*(0,\infty) \) over \( \partial A \), by Theorem 3.7. Since \( \Gamma^*(0,\rho_{-\gamma}) \leq \Gamma^*(0,\infty) \implies \Gamma^*(0,\rho_{-\gamma}) \geq \Gamma^*(0,\infty) \), it follows that \( \Gamma^*(0,\rho_{-\gamma})(\bar{x}_0) > \Gamma^*(0,\infty)(x_0) \).

If \( \bar{x}_0 = x_0 \), then \( \Gamma^*(0,\rho_{-\gamma})(\bar{x}_0) > \Gamma^*(0,\infty)(x_0) \) by Theorem 6.1.

Thus, in either case, \( \Gamma^*(0,\rho_{-\gamma})(\tilde{x}_0) > \Gamma^*(0,\infty)(x_0) \), and this implies
\[
\inf_{x \in \partial A} \Gamma^*(0,\rho_{-\gamma})(x) = \Gamma^*(0,\rho_{-\gamma})(\tilde{x}_0) > \Gamma^*(0,\infty)(x_0) = \inf_{x \in \partial A} \Gamma^*(0,\infty)(x).
\] (6.21)

The proof of (6.20) with \( \Gamma^*_{(\rho+\gamma,\infty)} \) in place of \( \Gamma^*_{(0,\rho_{-\gamma})} \) is identical. \( \square \)

By the assertion and (6.19) we obtain
\[
\limsup_{\epsilon \to 0} \epsilon \log P \{ |T^\epsilon(A) - \rho| > \gamma | T^\epsilon(A) < \infty \} \leq -t, \text{ some } t > 0,
\] (6.22)
which establishes the theorem. \( \square \)

The technique used to prove Theorem 2 can be adapted to establish a law of large numbers for \( Y_{T^\epsilon(A)} = \) the place of first passage, as follows.

Proof of Theorem 3. Let \( x_0 \) be the element given in Theorem 3.4 (i) when \( f = \Gamma^*_{(0,\infty)} \) and \( \mathcal{E} = A \), and let
\[
A_\gamma = A \cap \{ x \in \mathbb{R}^d : \| x - x_0 \| > \gamma \}
\]
[a subset of \( A \) which omits a small \( \gamma \)-ball about \( x_0 \)]. Then, by definition of conditional expectation,
\[
P \left\{ \left\| Y^\epsilon_{T^\epsilon(A)} - x_0 \right\| > \gamma \mid T^\epsilon(A) < \infty \right\}
\]
\[
= P\{\text{first hitting } A \text{ at a point of } A_\gamma\} / P\{\text{ever hitting } A\}
\]
\[
\leq P\{\text{ever hitting } A_\gamma\} / P\{\text{ever hitting } A\}
\]
\[
= P\{T^\epsilon(A_\gamma) < \infty\} / P\{T^\epsilon(A) < \infty\}.
\] (6.23)

Hence
\[
\limsup_{\epsilon \to 0} \epsilon \log P \left\{ \left\| Y^\epsilon_{T^\epsilon(A)} - x_0 \right\| > \gamma \mid T^\epsilon(A) < \infty \right\}
\]
\[
\leq - \inf_{\tau \in [0,\infty)} T^\epsilon_{A_\gamma}(\tau) + \inf_{\tau \in [0,\infty)} L_A(\tau)
\]
\[
= - \inf_{x \in \partial A_\gamma} \Gamma^*_{(0,\infty)}(x) + \inf_{x \in \partial A} \Gamma^*_{(0,\infty)}(x)
\] (6.24)
by Theorem 1 and Remark 2.2, and Theorems 3.1, 3.2, and the assumptions on $A$. The proof will be complete once we establish:

**Assertion.** $\inf_{x \in \text{cl} A^\gamma} \Gamma^*_x(x) > \inf_{x \in \text{cl} A^\gamma} \Gamma^*_x(x)$.

**Proof.** If $\inf_{x \in \text{cl} A^\gamma} \Gamma^*_x(x) = \infty$ the result is obvious, so from now on we will assume $\inf_{x \in \text{cl} A^\gamma} \Gamma^*_x(x) < \infty$.

Form a sequence $\{x_i\}_{i \in \mathbb{Z}_+} \subset A^\gamma$ such that

$$\Gamma^*_x(x) \downarrow \inf_{x \in \text{cl} A^\gamma} \Gamma^*_x(x) \text{ as } i \uparrow \infty. \quad (6.25)$$

Note that $\Gamma^*_x$ has compact level sets on $(\text{cone } B)^c$ [as in Remark 3.5 (i)] and $A \subset (\text{cone } B)^c$ [hypothesis (H2)]. Hence the sequence $\{x_i\}_{i \in \mathbb{Z}_+}$ is bounded and, consequently, a subsequence of $\{x_i\}_{i \in \mathbb{Z}_+}$ converges to some $z \in \text{cl } A^\gamma$. Since $\Gamma^*_x$ is lower semicontinuous,

$$\Gamma^*_x(z) \leq \liminf_{i \to \infty} \Gamma^*_x(x_i) = \inf_{x \in \text{cl} A^\gamma} \Gamma^*_x(x) \quad (6.26)$$

Next observe $z \in \text{cl } A^\gamma \implies z \neq x_0$. Since $x_0$ is the unique element which minimizes $\Gamma^*_x$ over $\text{cl } A$, by Theorem 3.7, it follows that

$$\inf_{x \in \text{cl } A^\gamma} \Gamma^*_x(x) < \inf_{x \in \text{cl } A^\gamma} \Gamma^*_x(x). \Box$$
