Abstract

Cells are regularly exposed to stress conditions that may lead to protein misfolding. To cope with this challenge, molecular chaperones selectively target structurally perturbed proteins for degradation via the ubiquitin-proteasome pathway. In mammals the co-chaperone BAG-1 plays an important role in this system. BAG-1 has two orthologues, Bag101 and Bag102, in the fission yeast Schizosaccharomyces pombe. We show that both Bag101 and Bag102 interact with 26S proteasomes and Hsp70. By epistasis mapping we identify a mutant in the conserved kinetochore component Spc7 (Spc105/Blinkin) as a target for a quality control system that also involves, Hsp70, Bag102, the 26S proteasome, Ubc4 and the ubiquitin-ligases Ubr11 and San1. Accordingly, chromosome missegregation of spc7 mutant strains is alleviated by mutation of components in this pathway. In addition, we isolated a dominant negative version of the deubiquitylating enzyme, Ubp3, as a suppressor of the spc7-23 phenotype, suggesting that the proteasome-associated Ubp3 is required for this degradation system. Finally, our data suggest that the identified pathway is also involved in quality control of other kinetochore components and therefore likely to be a common degradation mechanism to ensure nuclear protein homeostasis and genome integrity.

Introduction

Various conditions may cause partial denaturation of cell proteins. Such proteins are either shielded from aggregation and refolded to the native state by molecular chaperones [1] or they are targeted for degradation via the ubiquitin-proteasome system (UPS) [2] [3] [4] [5] [6] [7].

Faults in this system may lead to a build-up of toxic protein species which may cause diseases, including neurodegenerative disorders such as Parkinson’s and Alzheimer’s disease. Conversely, chaperone-assisted degradation of proteins that are structurally perturbed, but still functional, has also been linked to disease, as in cystic fibrosis [8].

At present, our understanding of what determines whether a chaperone commits to a folding or a degradation mode is limited. However, studies suggest that association with certain regulatory co-chaperones contributes to this process [9] [3]. The human BAG-1 anti-apoptotic protein is one such cofactor for Hsp70-type chaperones [10]. The BAG-1 co-chaperone functions as a nucleotide exchange factor for the chaperone and triggers the release of bound clients [10] [11] [12]. This substrate release is triggered by the BAG domain in BAG-1, which binds to the ATPase domain of Hsp70 [10] [13] [11]. Thus, when BAG-1 associates with the 26S proteasome via its N-terminal ubiquitin-like (UBL) domain, chaperone-bound clients are released and degraded [10] [13] [14] [11]. For efficient degradation, chaperone clients must first be ubiquitylated. In mammalian cells this is accomplished by the E2 ubiquitin conjugating enzyme, Ubc4, and the E3 ubiquitin-protein ligase, CHIP [14] [15] [16]. Importantly, chaperone-assisted degradation of certain clients is not affected in CHIP-deficient mammalian cells [17], suggesting that other, unidentified, ubiquitin ligases maintain chaperone-assisted degradation in the absence of CHIP [18]. Since the human genome encodes hundreds of E3s, identifying these ubiquitin ligases might be more straightforward in a simpler and genetically more tractable model organism. A database search for orthologues of human BAG-1 in the fission yeast, Schizosaccharomyces pombe, revealed two BAG-1 homologues, Bag101 and Bag102. Here, we show that Bag101 and Bag102 localize to the cytosol and nuclear envelope, respectively. Both proteins associate with the 26S proteasome and Hsp70 chaperones. By systematic high-throughput genetic screening, we identified a mutant version of the Spc7 protein, Spc7-23, as a substrate for chaperone-assisted degradation in S. pombe. Spc7 belongs to the Spc105-KNL-1-Blinkin-Spc7 family, which comprises an essential component of the kinetochore, a macromolecular structure that mediates bipolar attachment of chromatids to spindle microtubules and controls mitosis [19]. Accordingly, the spc7-23 mutant displays severe defects in chromosome segregation at the restrictive temperature [20]. In a bag102Δ background, the temperature-sensitive growth...
Author Summary

The accumulation of misfolded proteins represents a considerable threat to the health of individual cells and has been linked to severe diseases, including cancer and neurodegenerative disorders. To cope with this threat, especially under stress conditions, cells have evolved efficient quality control mechanisms. In general, these rely on molecular chaperones to either seize and refold misfolded proteins, or target them for degradation via the ubiquitin-proteasome system. At present, our understanding of what determines whether a chaperone commits to a folding or a degradation mode is limited. However, studies suggest that association with certain regulatory co-chaperones contributes to this process. Here, we show that certain BAG-1-type co-chaperones function in quality control by targeting misfolded kinetochore components for proteolysis. The presented genetic and biochemical data show that specific ubiquitin conjugating enzymes and ubiquitin-protein ligases maintain nuclear protein homeostasis and are required for upholding genome integrity.

Results

The fission yeast BAG domain proteins are homologues of human BAG-1

A database search for orthologues of human BAG-1 revealed that the fission yeast \textit{S. pombe} encodes two UBL/BAG domain proteins, Bag101 and Bag102. The budding yeast, \textit{Saccharomyces cerevisiae}, on the other hand, encodes only one BAG domain protein, Snl1. However, Snl1 does not contain any UBL domain (Fig. S1).

Like human BAG-1, the fission yeast BAG proteins both contain an N-terminal UBL domain and a C-terminal BAG domain (Fig. 1A). Overall, the fission yeast proteins show about 20\% sequence identity and 45\% sequence homology to the small (hBAG-1S) isoform of human BAG-1 (Fig. S1).

Bag101 and Bag102 interact with Hsp70-type chaperones

In humans, BAG domain proteins were found to associate with Hsp70 chaperones via their BAG domains [9]. To test whether this was also the case for the \textit{S. pombe} orthologues, the full length and truncated GST fusion proteins were produced in \textit{E. coli} (Fig. 1A) and immobilized to glutathione Sepharose. Since Bag102 is predicted to contain a single transmembrane (TM) domain near the N-terminus, we deleted the first 31 amino acids to circumvent the ubiquitin-proteasome system. At present, our understanding of what determines whether a chaperone commits to a folding or a degradation mode is limited. However, studies suggest that association with certain regulatory co-chaperones contributes to this process. Here, we show that certain BAG-1-type co-chaperones function in quality control by targeting misfolded kinetochore components for proteolysis. The presented genetic and biochemical data show that specific ubiquitin conjugating enzymes and ubiquitin-protein ligases maintain nuclear protein homeostasis and are required for upholding genome integrity.

Bag101 and Bag102 associate with the 26S proteasome

Previously, several UBL domain proteins, including mammalian BAG-1, have been found to interact with 26S proteasomes [21] [13] [22] [23]. To map the interaction between the fission yeast UBL/BAG domain proteins and the 26S proteasome, the pull down samples (Fig. 1B) were also probed for the presence of 26S proteasomes using antibodies to the Rpn11 ZZ-tag and the 20S particle \(\alpha\) subunits. In accordance with our expectations, full length Bag101 and Bag102 precipitated 26S proteasomes from the extracts (Fig. 1B) and the N-terminal UBL domains were necessary and sufficient to mediate the interaction (Fig. 1B). However, the proteasome binding of Bag102 appeared reduced compared to Bag101 (Fig. 1B).

To test if the UBL/BAG proteins also associate with 26S proteasomes \textit{in vivo}, we performed co-immunoprecipitation experiments from cells expressing C-terminally Flag-tagged Bag101 and Bag102. We found that both Bag101 and Bag102 co-precipitated with 26S proteasomes (Fig. 1C). Together, these data imply that Bag101 and Bag102 associate with 26S proteasomes in a UBL domain dependent manner.

Subcellular localization of Bag101 and Bag102

Next we examined the subcellular localization of Bag101- and Bag102-GFP fusion proteins. Bag101 was present throughout the cytosol and nucleus, but clearly enriched in several cytosolic spots (Fig. 1D). Bag102, on the other hand, localized to the nuclear/ER membrane (Fig. 1D), similar to 26S proteasomes [24]. Thus, one would predict that the Bag102 protein functions on the cytosolic and nuclear side of the nuclear/ER membrane, and not in the ER lumen. Accordingly, the Bag102 UBL and BAG domains should face the cytosol and nucleus. To test this prediction, microsomes were isolated from cells expressing Bag102 with a C-terminal Flag epitope and analyzed by blotting. In accordance with Bag102 containing a transmembrane domain, all Bag102 was associated with the microsome pellet (Fig. 1E). The membrane fraction only contained trace amounts of the soluble control protein Dph1 (Fig. 1E). Upon treating the microsomes with protease K, the ER luminal protein Bip1 was not affected, suggesting that the isolated microsomes were intact (Fig. 1E). However, the signal from the C-terminal Flag epitope on Bag102 was completely lost (Fig. 1E), so we conclude that Bag102 is a nuclear membrane protein that is oriented with the C-terminus facing the cytosol and/or nucleus.

Epistatic miniaarray profiling identifies Spc7-23 as a substrate for chaperone-assisted degradation

To further characterize the functions of Bag101 and Bag102 \textit{in vivo}, bag101- and bag102-null mutants were constructed by PCR mutagenesis. Curiously, neither the bag101\(\Delta\) nor the bag102\(\Delta\) strain displayed any obvious growth phenotypes at 25\(^\circ\)C or 37\(^\circ\)C.
A bag101\textsuperscript{D} and bag102\textsuperscript{D} double mutant also appeared as wild type (Fig. S2). Therefore, we performed an epistatic miniarray profiling (E-MAP) screen \cite{25} on bag101\textsuperscript{D} and bag102\textsuperscript{D} mutants. By robotics, the bag101\textsuperscript{D} mutant was systematically crossed to a collection of 393 other \textit{S. pombe} mutants, while the bag102\textsuperscript{D} strain was crossed to 540 mutants. This collection of mutants contained primarily verified null mutants where the coding sequence had been replaced with a nourseothricin resistance (clonNAT) cassette, but also included a few point mutants in essential genes with the clonNAT cassette inserted next to the mutant gene. The double mutant progeny was then scored for growth. Neither bag101\textsuperscript{D} nor bag102\textsuperscript{D} was found to display any strong negative genetic (synthetic sick/lethal) interactions with the mutants included in the screen. However, bag101\textsuperscript{D} and bag102\textsuperscript{D} did show some positive genetic interactions (synthetic rescue phenotypes) with certain mutants (Table 1 and Table 2). In particular, we noted that both bag101\textsuperscript{D} and bag102\textsuperscript{D} presented a synthetic rescue phenotype with a point mutant, spc7-23 (Table 1 and Table 2), in the essential kinetochore component called Spc7 in \textit{S. pombe} \cite{26} \cite{20}, Spc105 in \textit{S. cerevisiae}, and Blinkin in higher eukaryotes.

We decided to have a closer look at the spc7-23 mutant. In agreement with what has been observed before \cite{20}, we found that the \textit{spc7-23} allele is temperature sensitive for growth (Fig. 2A) and...
found that Spc7 (and Spc7-23) migrated faster in SDS-PAGE. We observed more Spc7-23 associated with Hsp70 at 30°C (153 kDa). In general, the chaperone requirement of proteins Bag101, is required for a nuclear chaperone-assisted degradation Hsp70 (Fig. 3D).

Degradation of Spc7-23 depends on the 26S proteasome

Additional information on this Spc7 degradation pathway came from an extragenic suppressor screen of the spc7-23 mutant phenotype [28]. One of the suppressing plasmids contained a genomic DNA fragment of chromosome II encoding a truncated version of the proteasome subunit Mts2/Rpt2, 5S rRNA, aspartate aminotransferase and a truncated version of the Mpr1 phosphotransferase. Digesting this plasmid with the PstI restriction enzyme generated a shorter construct encoding only the first 658 bp (219 aa) of mts2'/RPT2 and first 95 bp of the 5S rRNA. The temperature sensitive phenotype of the spc7-23 strain transformed with this plasmid was repressed (Fig. 4A). Expression of the Mts2/Rpt2 truncation in a wild type background resulted in a temperature sensitive phenotype (Fig. 4A). Since the C-termini of proteasome Rpt subunits are critical for 26S proteasome assembly and function [29], expression of the truncated proteasome subunit Mts2/Rpt2 is likely to impede degradation of Spc7-23, thus restoring Spc7-23 protein levels and alleviating the growth and DNA segregation defects. Indeed, expression of the truncated Mts2 led to an increase in ubiquitin-protein conjugates (Fig. S6). To test the effect of proteasome mutants further, we crossed the Mts2 led to an increase in ubiquitin-protein conjugates (Fig. S6). To test the effect of proteasome mutants further, we crossed the spc7-23 bag101 Δ double mutant with null mutants in bag101 Δ and bag102 Δ (Tables 1 and 2), and the association of BAG proteins with the 26S proteasome suggest that when the BAG proteins are lacking, Spc7-23 degradation is impaired, and growth therefore restored. To test this hypothesis, we first set out to verify the result of the E-MAP screen. We combined the spc7-23 mutation with null mutants in bag101 Δ and bag102 Δ. In the case of the spc7-23 bag101 Δ, we did not observe any synthetic rescue of the temperature sensitive phenotype (Fig. 3A), indicating that bag101 Δ was a false positive in the E-MAP screen. However, growth of the spc7-23 bag102 Δ double mutant was completely restored at 30°C (Fig. 3A), and ectopic expression of the Bag102-GFP fusion protein reversed this effect (Fig. S3).

Using live cell imaging we determined if kinetochore targeting of Spc7-23-GFP was altered in a bag102 deletion background. Spc7-GFP and Spc7-23-GFP can be seen as one single fluorescent signal per interphase cell grown at 25°C (Fig. 3B). However at the non-permissive temperature of 30°C the mutant Spc7-23-GFP protein is no longer kinetochore targeted. This abnormal phenotype was suppressed in a bag102 Δ background (Fig. 3B, Fig. S4, Fig. S5).

We then asked if the DNA segregation defect of the spc7-23 mutant was also suppressed in the bag102 Δ background. At the restrictive temperature, the spc7-23 single mutant displayed an uneven DNA distribution in approximately 70% of the mitotic cells (Fig. 3C), while in the spc7-23 bag102 Δ strain this was reduced to less than 15% (Fig. 3C).

If Spc7-23 is indeed a substrate for chaperone-assisted degradation, one would expect Spc7-23 to be associated with molecular chaperones such as Hsp70. To test this prediction, we immunoprecipitated Spc7 and Spc7-23 from S. pombe lysates at either 4°C or 30°C. As has been noted before [27] [20] [28], we found that Spc7 (and Spc7-23) migrated faster in SDS-PAGE gels than predicted from the calculated molecular weight (153 kDa). In general, the chaperone requirement of proteins is more stringent at higher temperatures. Accordingly, we observed more Spc7-23 associated with Hsp70 at 30°C than at 4°C (Fig. 3D). Also, the interaction between Spc7-23 and Hsp70 appeared much stronger than between wild type Spc7 and Hsp70 (Fig. 3D).

Together, these data support a model where Bag102, but not Bag101, is required for a nuclear chaperone-assisted degradation mechanism that ensures kinetochore integrity.

Table 2. Quantitative epistatic miniarray profiling for bag102 Δ.

doi:10.1371/journal.pgen.1004140.t002
ubiquitylation during Spc7-23 degradation. (Fig. 4G), suggesting that Bag102 functions at a step after
strain did contain increased amounts of ubiquitylated Spc7-23
detection by a quality control system and targeted for proteasomal
temperature, the mutant, but functional, Spc7-23 protein is
fission yeast (Fig. 4F).
we found that Bortezomib at 100
amounts of Bortezomib (Fig. 4F). As has been shown before [30],
restrictive temperature was restored on media containing sublethal
cultures, where protein synthesis was blocked with cycloheximide.
To test this hypothesis, we followed the degradation of Spc7-23 in
part, caused by increased degradation of the Spc7-23 protein. To
test this hypothesis, we followed the degradation of Spc7-23 in
cultures, where protein synthesis was blocked with cycloheximide.
Indeed, Spc7-23 protein appeared stable at the permissive
temperature (Fig. 4E). Moreover, this degradation was mediated by the
UPS, since it was blocked by the proteasome inhibitor Bortezomib
(BZ) (Fig. 4E). Accordingly, growth of the spc7-23 strain at the
restrictive temperature was restored on media containing sublethal
amounts of Bortezomib (Fig. 4F). As has been shown before [30],
we found that Bortezomib at 100 μM was not toxic to wild type
fission yeast (Fig. 4F).
Together, these data suggest a model where, at the restrictive
temperature, the mutant, but functional, Spc7-23 protein is
detected by a quality control system and targeted for proteasomal
degradation.

Spc7-23 is ubiquitylated in proteasome and bag102
mutants
To analyze this model further we decided to test the
ubiquitylation status of Spc7-23. Cells were transformed with
expression vectors for Spc7-23 and 6His-tagged ubiquitin. The
ubiquitin was then precipitated under denaturing conditions (in 8
M urea), resolved by SDS-PAGE and analyzed by blotting. In
agreement with the 26S proteasome being necessary for Spc7-23
degradation, Spc7-23 was ubiquitylated in both the mts2-1 and
nas6Δ backgrounds (Fig. 4G). No ubiquitylated Spc7-23 was
detected in the bag102Δ cells (Fig. 4G). However, the bag102Δ
strain did contain increased amounts of ubiquitylated Spc7-23
(Fig. 4G), suggesting that Bag102 functions at a step after
ubiquitylation during Spc7-23 degradation.

Degradation of Spc7-23 depends on the E2 ubc4
The data obtained so far suggest that kinetochore integrity is
controlled by a chaperone-assisted degradation pathway involving
the 26S proteasome, Hsp70 and the co-chaperone Bag102. In
order to further characterize this degradation pathway, we aimed at
identifying the E2 and E3 enzymes involved in the ubiquitylation
reaction. Although S. pombe does not contain a CHIP
orthologue, CHIP’s cognate E2, Ubc4 [15], is present in this
organism, making it a favored candidate for the degradation
pathway. In order to identify the E2 involved in an unbiased
fashion, we obtained deletion or conditional mutants in 11 of S.
pombe’s ubiquitin-specific E2s and crossed them individually to the
spc7-23 strain to obtain double mutants. The rhp6Δ mutant,
however, was very sick and we were unable to obtain a double
mutant with spc7-23. Of the remaining 10 different E2spc7-23
mutants, only the ubc4-1spc7-23 mutant was viable at the restrictive
temperature (Fig. 3A), suggesting that Ubc4 is indeed the sole or at
least primary E2 ubiquitin conjugating enzyme involved in this
degradation pathway.

Degradation of Spc7-23 depends on the E3s Ubr11 and
San1
In mammalian cells, chaperone-assisted degradation is generally
thought to occur via the E3 ubiquitin-protein ligase, called CHIP.
However, as mentioned, yeast cells do not encode any obvious
CHIP orthologues. We therefore hypothesized that the relevant
E3(s) involved in degradation of Spc7-23 are likely specific for
misfolded proteins [18], and would localize to the nucleus or
nuclear envelope and be induced by stress conditions such as high
temperatures. These parameters led us to select 6 E3 candidates
from available transcriptomics [31] and localization data [32]:
Ubr1, Ubr11, Hul5, San1, Doa10 and Hrd1.

We then tested if null mutants in any of these E3s could suppress
the temperature sensitive phenotype of the spc7-23 strain. We found
that growth at the restrictive temperature was fully restored in the
spc7-23ubr11Δ and spc7-23san1Δ double mutants (Fig. 5B), but not
in the spc7-23ubr1Δ, spc7-23hul5Δ and spc7-23doa10Δ strains
(Fig. 5B). The spc7-23ubr1Δ mutant appeared less fit than the single
mutants at the permissive temperature. For the spc7-23hul5Δ strain,
growth was only partially restored at the restrictive temperature
(Fig. 5B). These results suggest that the primary E3s involved in
spc7-23 turnover are Ubr1 and San1. Accordingly, the uneven
DNA segregation of the spc7-23 strain was also strongly reduced in
the spc7-23ubr11Δ and spc7-23san1Δ double mutants (Fig. 5C).
To further analyze the genetic interactions between ubr11, san1 and
spc7-23, we isolated V5-tagged Ubr11 and Flag-tagged San1 by
immunoprecipitation. We were unable to detect any V5-Ubr11 in
extracts, but the protein was clearly enriched after precipitation
(Fig. 5D). For both Ubr11 and San1 we found that Spc7-23, but not
wild type Spc7, co-precipitated with the E3s when proteasome
activity was inhibited with Bortezomib (Fig. 5D and Fig. 5E).
Finally, the increased ubiquitylation of Spc7-23 in response to
Bortezomib was markedly decreased in the ubr11Δ strain, and also
lowered in the san1Δ mutant (Fig. 5F), further corroborating that

Figure 2. spc7-23 cells are temperature sensitive and defective in DNA segregation. (A) The growth of wild type and spc7-23 cells on solid
media was compared at the indicated temperatures. (B) Cells carrying the mutant spc7-23 mutation were incubated at 25°C or 30°C and stained to
visualize DNA (blue) and tubulin (green). Note that the DNA segregation becomes unequal at the restrictive temperature.
doi:10.1371/journal.pgen.1004140.g002
Spc7-23 is a target for Ubr11- and San1-catalyzed ubiquitylation and degradation.

Degradation of Spc7-23 is regulated by the deubiquitylating enzyme Ubp3

In a suppressor analysis of the spc7-23 mutant phenotype, we identified a truncated cDNA of the Ubp3 deubiquitylating enzyme (DUB). This truncated version of Ubp3 (Ubp3-W466X) lacks the last 47 residues of the enzyme, that includes part of the catalytic UCH domain, and therefore most likely functions as a dominant negative allele. To test this further, we transformed the spc7-23 strain with either a control plasmid, or expression constructs for wild type full-length Ubp3 or the Ubp3-W466X truncation isolated in the screen. Indeed, expression of Ubp3-W466X restored growth at the restrictive temperature (Fig. 6A) while overexpression of wild type Ubp3 aggravated the growth defect (Fig. 6A). In agreement with this, deletion of ubp3 almost completely restored growth (Fig. 6B) and alleviated the DNA segregation defect (Fig. 6C) of the spc7-23 strain at the non-permissive temperature. These data suggest that Ubp3 stimulates degradation of Spc7-23. In general, DUBs counter protein degradation. However, a few DUBs have been found to promote protein degradation. These are typically associated with the 26S proteasome.

Spc7-23 is a target for Ubr11- and San1-catalyzed ubiquitylation and degradation.

Degradation of Spc7-23 is regulated by the deubiquitylating enzyme Ubp3

In a suppressor analysis of the spc7-23 mutant phenotype, we identified a truncated cDNA of the Ubp3 deubiquitylating enzyme (DUB). This truncated version of Ubp3 (Ubp3-W466X) lacks the last 47 residues of the enzyme, that includes part of the catalytic UCH domain, and therefore most likely functions as a dominant negative allele. To test this further, we transformed the spc7-23 strain with either a control plasmid, or expression constructs for wild type full-length Ubp3 or the Ubp3-W466X truncation isolated in the screen. Indeed, expression of Ubp3-W466X restored growth at the restrictive temperature (Fig. 6A) while overexpression of wild type Ubp3 aggravated the growth defect (Fig. 6A). In agreement with this, deletion of ubp3 almost completely restored growth (Fig. 6B) and alleviated the DNA segregation defect (Fig. 6C) of the spc7-23 strain at the non-permissive temperature. These data suggest that Ubp3 stimulates degradation of Spc7-23. In general, DUBs counter protein degradation. However, a few DUBs have been found to promote protein degradation. These are typically associated with the 26S
Figure 4. Spc7-23 is degraded via the ubiquitin-proteasome pathway. (A) The growth on solid media of wild type (lower panel) and spc7-23 cells (upper panel) transformed with either a control vector (vector) or PstI digested genomic DNA construct encoding mts2-219X was compared at different temperatures. (B) The growth of wild type, mts2-1, spc7-23 and the mts2-1spc7-23 double mutant was compared at the indicated temperatures. (C) The growth on solid media of wild type, nas6Δ, spc7-23 and the nas6Δspc7-23 double mutant was compared at the indicated temperatures. (D) Equal (wild type) or unequal DNA segregation was quantified in spc7-23-gfp and spc7-23-gfp nas6Δ cells at 30 °C. ** p < 0.01 (Welch test) for the spc7-23-gfp nas6Δ strain compared to the spc7-23-gfp strain. For spc7-23-gfp (n = 200) and spc7-23-gfp nas6Δ (n = 100) late anaphase cells. Note that wild type DNA segregation is re-established in the spc7-23nas6Δ double mutant. (E) The amount of Spc7-23 protein was followed in cultures at 27 °C and 30 °C where protein synthesis was inhibited with 100 μg/mL cycloheximide (CHX) for 4 hours. To some cultures 1 mM of the proteasome inhibitor Bortezomib (BZ) was also added. Equal loading was checked using antibodies to tubulin. (F) The growth on solid media of wild type and spc7-23 cells was compared at the indicated temperatures in the absence (control) or presence of 100 μM BZ. (G) Strains with the indicated BAG Domain Proteins in Kinetochore Degradation
proteasome, where release of the ubiquitin chain is required for efficient degradation [33] [34] [35]. Accordingly, we observed that 26S proteasomes co-precipitated with Ubp3 (Fig. 6D), as has been seen before [33], and that Spc7-23 was ubiquitylated in the spc7 null mutant (Fig. 6E).

Other components follow the same degradation pathway

To further characterize this quality control system we decided to analyze if other kinetochore components follow the same degradation pathway as Spc7-23. To this end, we analyzed the temperature sensitive mis6-302 and mal2-1 mutant strains. Both Mis6 and Mal2 are part of the Sim4 kinetochore subcomplex [36] while Spc7 is part of the NMS complex. When these mutations were combined with ubr11 (Fig. 7A and Fig. 7B) viability was only restored at the restrictive temperature for the mal2-1 strains. However, in case of san1A, viability at the restrictive temperature was restored for both the mis6-302 and mal2-1 strains (Fig. 7C and Fig. 7D). Mutation of ubc4 also increased the viability of the mis6-302 and mal2-1 strains at the restrictive temperatures (Fig. 7E and Fig. 7F), as did deletion of bag102, although the effect was more modest than that observed for spc7-23 (Fig. 7G and Fig. 7H).

This suggests that the degradation pathway, described here, is part of a more general control system that monitors the quality of several nuclear proteins, and especially kinetochore proteins.

Discussion

Here, we describe a chaperone-assisted degradation pathway involved in nuclear protein quality control. Presumably this pathway targets a broad range of misfolded nuclear proteins, and not only kinetochore proteins. However, considering the extreme biological importance and complex nature of kinetochores, it is perhaps not surprising that a quality control system is involved in monitoring kinetochore integrity.

The precise transmission of chromosomes during cell division is a complex process that is highly regulated on several levels by kinetochores, which form a platform for checkpoint proteins, control microtubule plus-end dynamics and provide mechanical attachment sites for the spindle. Given the monumental tasks of a kinetochore, it is not surprising that these are complex structures of up to 100 different proteins that are organized in specific evolutionarily conserved subcomplexes. Although the composition of kinetochores is flexible to a certain degree, most kinetochore proteins are essential and distinct deviations from physiological levels of such proteins will lead to chromosome missegregation and aneuploidy [20] [37]. The folding, stoichiometry, and assembly of kinetochore components must therefore be tightly controlled. If the amount of a kinetochore component is insufficient or the protein is misfolded, complex formation may become blocked and chromosome segregation rendered defective. Accordingly, molecular chaperones play important roles in the biogenesis of functional kinetochores [38]. In general, proteins that do not pass inspection of chaperones are discarded via the UPS [18]. Data suggest that such quality control systems follow a better-safe-than-sorry principle, and are thus prone to target proteins that, albeit being structurally perturbed, are still functional. One example of this is in cystic fibrosis, where the degradation of certain mutant, but functional, versions of the chloride channel, CFTR, leads to a lowered amount of channel protein and manifestation of the disease [39]. Examples such as this have been instrumental for mapping of chaperone-assisted degradation pathways [18] and have recently been applied in linking the budding yeast E3, Ubr2, with regulating the stoichiometry of the budding yeast specific kinetochore component Dsn1 [40], presumably by a pathway related to the one described here. Intriguingly, some data suggest that not all kinetochore components follow the same degradation pathway. Previous studies focusing on the budding yeast kinetochore component Ndc10 have shown that an Ndc10 mutant that is only mildly structurally perturbed [41] is degraded via the ER-associated E3 ligase Doa10 [42]. The Ndc10 degron has also been defined, and is targeted by the Hsp70 chaperone Ssa1 [41].

Studies in mammalian cells have revealed that Bag-1 interacts with the 26S proteasome and Hsp70 [9] [3], thereby physically bridging the two major mechanisms for intracellular quality control, the degradation and refolding pathways. In essence, this also places BAG-1 at the centre of chaperone-assisted degradation. Hence, when chaperone clients cannot be refolded to their native conformation, E3 ligases, such as CHIP, first ubiquitylate them, while Bag-1 directs them for degradation by the UPS [9] [3]. Normally, substrate specificity is provided by the E3 ubiquitin ligase. However, the E3s involved in chaperone-assisted degradation appear to generally outsource substrate recognition to chaperones and co-chaperones [9] [3], thereby utilizing a pre-existing cellular system for recognition of misfolded proteins. Thus, in higher eukaryotes Hsp70s provide the substrate specificity by bringing the Hsp70 clients into proximity with the Hsp70-binding E3 ligase CHIP, before BAG-1 mediates the substrate release at the 26S proteasome [3] [5]. Exactly how this is accomplished for other E3s, such as Ubr11 is not known, but since Ubr11 interacts with Hsp70 [43], and the data presented here suggest that the role of UBL/BAG proteins is conserved, it is likely that the substrate selection and proteasomal delivery occurs by a similar mechanism. In regard to substrate specificity, San1, constitutes an exception from this rule, in that it, via intrinsically disordered areas, directly associates with a range of misfolded proteins [44]. However, certain San1 targets still associate with chaperones [43] and may require co-chaperones for proteasomal targeting [46].

Since targeted gene disruption of BAG-1 in mice leads to early embryonic lethality, due to massive cell death in the liver and severe defects in the differentiation and survival of neuronal cells [47], we were surprised to find that neither bag101 nor bag102 null mutants displayed any obvious phenotypes. However, yeast null mutants in other bona fide proteasome substrate targeting factors, such as Rhp23/Rad23 and Dph1/Dsk2, also do not display strong phenotypes, indicating a high level of redundancy in their in vivo functions [48].

Mammalian BAG-1 has been shown to interact with Hsp70-type chaperones via its BAG domain [10], and the structure of the BAG domain, bound to the ATPase domain of mammalian Hsp70, has been solved [11]. In S. pombe, we find that both Bag101 and Bag102 interact with Hsp70 via their BAG domain. Hence, biochemically, the Bag101 and Bag102 co-chaperones appear to exert similar functions. However, since only a mutant lacking Bag102 was able to suppress the phenotypes of the spc7-23 strain and restore Spc7-23 protein levels, Bag101 and Bag102 appear to
harbour separate and specific cellular functions. This is reflected by the difference in subcellular localization of Bag101 and Bag102. We found Bag102 at the nuclear membrane, presumably like 26S proteasomes [49], along the inside of the nuclear envelope, while Bag101 was mainly cytosolic.

We observed that the spc7-23 phenotypes can also be alleviated by compromising other components of the chaperone-assisted degradation machinery. These data fit with a model where the Spc7-23 protein is slightly misfolded, but still functional, at the restrictive temperature. However, the surveillance system targets

Figure 5. Spc7-23 degradation depends on Ubc4, Ubr11 and San1. (A) The growth of the indicated strains on solid media was compared at 25 °C (upper panel) and 30 °C (lower panel); (B) The growth of the indicated strains on solid media was compared at 25 °C (left panel) and 30 °C (right panel). (C) Equal (wild type) or unequal DNA segregation was quantified in spc7-23-gfp ubr11Δ and spc7-23-gfp san1Δ cells at 30 °C. ** p < 0.01 (Welch test) for the spc7-23-gfp ubr11Δ and spc7-23-gfp san1Δ strains compared to the spc7-23-gfp strain. For spc7-23-gfp (n = 200) and spc7-23-gfp ubr11Δ (n = 100) and spc7-23-gfp san1Δ (n = 100) late anaphase cells. Note that wild type DNA segregation is re-established in the spc7-23ubr11Δ and spc7-23san1Δ double mutants. (D) V5-tagged Ubr11 was immunoprecipitated from cells treated with Bortezomib (BZ) using antibodies to V5 or control antibody. The precipitated material was analyzed by SDS-PAGE and blotting for V5 (Ubr11) and HA (Spc7). (E) Flag-tagged San1 was immunoprecipitated from cells treated with Bortezomib (BZ) using antibodies to Flag or control antibody. The precipitated material was analyzed by SDS-PAGE and blotting with antibodies to the HA-tag on Spc7-23. The arrowhead marks the position where non-ubiquitylated Spc7-23 migrates. Note that ubiquitylated Spc7-23 species are less abundant in ubr11Δ and san1Δ mutants.

the protein for Ubr11- and San1-mediated ubiquitylation and proteasome-dependent degradation. This, in turn, leads to a reduced cellular level of the misfolded protein and manifestation of the phenotype (Fig. 8).

DUBs counter ubiquitylation and therefore play an important regulatory role in the UPS [50]. Our biochemical and genetic data and implicates the DUB, Ubp3, in promoting chaperone-assisted degradation. This effect is often tied to proteasome-associated DUBs that do not deubiquitylate the substrate until the substrate is committed to degradation [34] [33] [35]. Accordingly, Ubp3 was recently found to associate with 26S proteasomes and stimulate protein degradation [33]. Our data on *S. pombe* Ubp3 support this model. To our knowledge, Ubp3 is the first example of a DUB functioning in degradation of kinetochore proteins.

Remarkably, the degradation of chaperone clients proceeds normally in CHIP-deficient mammalian cells [17], suggesting that other ubiquitin ligases exert functions that overlap with CHIP during chaperone-assisted degradation. Though several candidates have been proposed [3], none of these are conserved to yeast. From the data presented here, we propose that Ubr11 functions in parallel with CHIP during chaperone-assisted degradation also in higher eukaryotes. Presumably due to its highly disordered structure and therefore poor sequence conservation, no San1 orthologue has yet been identified in higher eukaryotes. Presumably due to its highly disordered structure and therefore poor sequence conservation, no San1 orthologue has yet been identified in higher eukaryotes. Indeed, only one sequence, predicted to be highly disordered, was identified in the *S. pombe* genome [56]. This sequence showed significant similarity to the human chaperone-assisted degradation pathway (see below), and it was found to associate with the proteasome [56]. However, the role of this protein in the *S. pombe* degradation pathway is unknown.

In conclusion, our data corroborate previous findings on mammalian BAG domain proteins [13] and reveal a so far unreported chaperone-assisted degradation pathway, involved in nuclear protein quality control and kinetochore integrity.

### Materials and Methods

*S. pombe* strains and techniques

Fission yeast strains used in this study (Table S1) are derivatives of the wild type heterothallic strains 972h[+] and 975h[−]. Some strains were purchased from Bioneer [51]. Standard genetic methods and media were used and *S. pombe* transformations were performed using lithium acetate [52]. The PCR mutagenesis was performed as described [53].

Plasmids

To generate Bag101 (SPBC16G5.11c) constructs, FL (full length), BAG domain (amino acids 78–190) and UBL domain (1–77) cDNAs were amplified from *S. pombe* genomic DNA and inserted into pDONR221 (Invitrogen) and pGEX-KG (GE Healthcare). Full length *bag102+ (SPBC300.9c), ΔTM* (31–206), BAG (122–206) and UBL (31–121) cDNAs were also inserted into the pDONR221 and pGEX-KG vectors. For expression in *S. pombe*, the inserts from the pDONR221 vectors were transferred to the pDUAL vector system [54] using Gateway cloning technology (Invitrogen). Both ubp3 variants were cloned via XhoI/NotI into the pJR2-3XL vector with the ura3-52 promoter [55]. The HA-tagged Spc7-23 construct was obtained by QuickChange site directed mutagenesis (Stratagene) on pJR-XU41 plasmid encoding Spcy-23HA. The expression construct for 6His-ubiquitin has been described before [56]. The expression construct for San1 was kindly provided by Dr Makoto Kawamukai [57].

Binding assays

The GST fusion proteins were expressed in *E. coli* BL21 (DE3) or *E. coli* Rosetta (DE3) and bound to glutathione Sepharose 4
beads (GE Healthcare) as described by the manufacturer. The protein/bead ratio was 1 mg/mL. Binding experiments were carried out using 20 μL of beads in 1 mL of 50% cleared (13000 g, 30 min.) extract from a strain expressing Pad1/Rpn11 with a Protein A ZZ-tag. The extract was prepared with glass beads in buffer A (25 mM Tris/HC1 pH 7.5, 50 mM NaCl, 2 mM MgCl2, 5 mM ATP, 10% glycerol, 0.1% Triton X-100, 2 mM DTT, 1 mM PMSF and Complete protease inhibitors (Roche)). After overnight tumbling at 4°C, the beads were washed 4 times in 10 mL buffer A and resuspended in 30 μL SDS sample buffer. 20 μL of the samples were analyzed on 12% SDS gels and subjected to Western blotting.

Immunoprecipitations were performed from 50 mL cultures in mid exponential phase. Cells were lysed using glass beads in 1 volume of buffer B (25 mM Tris/HCl pH 7.5, 100 mM NaCl, 10% glycerol, 1 mM PMSF and Complete protease inhibitors (Roche)) and cleared by centrifugation (13000 g, 30 minutes). The soluble fraction was tumbled end-over-end for 4 hours at 4°C with 1 μL of antibody to V5 (Invitrogen), Flag (Sigma) or HA (Sigma) and 20 μL protein G Sepharose (GE Healthcare). A monoclonal antibody of the same isotype but reacting with human α2-macroglobulin was used as a negative control [58]. The beads were then washed 4 times in 10 mL of buffer B and resuspended in 30 μL SDS sample buffer. 20 μL of the samples were separated on 12% SDS gels and subjected to Western blot analysis. All ubiquitin blots were boiled for 5 minutes prior to blocking to enhance immunoreactivity.

The antisera, used in Western blots, were affinity purified rabbit polyclonal anti-Mts4, mouse monoclonal MCP231 to 20S proteasome 2 subunits (Enzo), 5A5 mouse monoclonal anti-Hsp70 (Abcam), mouse monoclonal anti-Flag (Sigma), mouse monoclonal anti-V5 (Invitrogen), rabbit anti-ubiquitin (DAKO Cytomation), TAT1 mouse monoclonal anti-tubulin (Abcam) and rat anti-HA (Roche). Secondary antibodies were purchased from DAKO Cytomation.

**Ubiquitylation of Spc7-23**

The ubiquitylation status of Spc7-23 was determined by precipitating 6His-ubiquitin under denaturing conditions, electrophoresis, and blotting for Spc7-23 as described previously [56].

**Growth assays**

Growth assays on solid media were performed essentially as described [24]. Briefly, the *S. pombe* strains to be assayed were grown to an OD600 nm of 0.4–0.8. The cells were then diluted in media to an OD600 nm of exactly 0.40. Serial 5-fold dilutions of this culture were prepared before 5 μL of each dilution was spotted on agarose pads as described [61]. All images in figure S3B were taken using the same conditions. Shown are maximum-intensity projections of 15 x slices with a distance of 0.5 μm using an argon laser (20% laser intensity, 400 ms exposure time). For figure S5 the following conditions were used: 50% DMSO, 5% 561 nm, 3% 405 nm laser intensity.

Signal intensity of GFP fluorescence were measured in a 10-by-10 pixel square (with subtraction of the fluorescent background) in n = 30 cells per strain and temperature with ImageJ 1.44 software (NIH) as described in [28].

**Supporting Information**

**Figure S1** Sequence similarity of human BAG-1S, Bag101, Bag102 and Sn1. GistralW alignments of human (*Hs*) BAG-1S, fission yeast (*S*) Bag101 (upper panel), Bag102 (middle panel) and budding yeast (*S*) Sn1 (lower panel). Identical and homologues...
residues are marked with (*) and (:), respectively. The domain organization is indicated by coloured bars.

**Figure S2** No apparent phenotype of bag101 and bag102 null mutants. The growth on solid media of wild type, bag101Δ, bag102Δ and bag101Δbag102Δ strains was compared at the indicated temperatures.

**Figure S3** Expression of Bag102-GFP reverses the bag102Δspc7-23 phenotype. Growth comparison on solid media of wild type and bag102Δspc7-23 cells transformed with empty vector or the bag102-GFPΔ thiamine regulated NMT1 expression vector.
