Relational Algebra by Way of Adjunctions

Jeremy Gibbons
(joint work with Fritz Henglein, Ralf Hinze, Nicolas Wu)
DBPL, October 2015
1. Summary

- bulk types (sets, bags, lists) are *monads*
- monads have nice *mathematical foundations via adjunctions*
- monads support *comprehensions*
- comprehension syntax provides a *query* notation

\[
\begin{align*}
\left[
& (\text{customer.name, invoice.amount}) \\
| & \text{customer} \leftarrow \text{customers}, \\
& \text{invoice} \leftarrow \text{invoices}, \\
& \text{customer.cid} = \text{invoice.customer}, \\
& \text{invoice.due} \leq \text{today}
\end{align*}
\]

- monad structure explains *selection, projection*
- less obvious how to explain *join*

2. Galois connections

Relating monotonic functions between two ordered sets:

\[(A, \leq) \parallel (B, \subseteq)\]

means \(f b \leq a \iff b \subseteq g a\)

For example,

\[(\mathbb{R}, \leq_{\mathbb{R}}) \parallel (\mathbb{Z}, \leq_{\mathbb{Z}})\]

“Change of coordinates” can sometimes simplify reasoning; eg rhs gives \(n \times k \leq m \iff n \leq m \div k\), and multiplication is easier to reason about than rounding division.
3. Category theory from ordered sets

A category $\mathcal{C}$ consists of

- a set* $|\mathcal{C}|$ of objects,
- a set* $\mathcal{C}(X, Y)$ of arrows $X \to Y$ for each $X, Y : |\mathcal{C}|$,
- identity arrows $id_X : X \to X$ for each $X$
- composition $f \cdot g : X \to Z$ of compatible arrows $g : X \to Y$ and $f : Y \to Z$,
- such that composition is associative, with identities as units.

Think of a directed graph, with vertices as objects and paths as arrows.

An ordered set $(A, \leq)$ is a degenerate category, with objects $A$ and a unique arrow $a \to b$ iff $a \leq b$.

```
... → -2 → -1 → 0 → 1 → 2 → ...
```

Many categorical concepts are generalisations from ordered sets.

*proviso...
4. Concrete categories

Ordered sets are a concrete category: roughly,

- the objects are sets with additional structure
- the arrows are structure-preserving mappings

Many useful categories are of this form.

For example, the category \textbf{CMon} has commutative monoids \((M, \otimes, \epsilon)\) as objects, and homomorphisms \(h: (M, \otimes, \epsilon) \rightarrow (M', \oplus, \epsilon')\) as arrows:

\[
\begin{align*}
  h (m \otimes n) &= h m \oplus h n \\
  h \epsilon &= \epsilon'
\end{align*}
\]

Trivially, category \textbf{Set} has sets as objects, and total functions as arrows.
5. Functors

Categories are themselves structured objects...

A functor $F : C \to D$ is an operation on both objects and arrows, preserving the structure: $F f : F X \to F Y$ when $f : X \to Y$, and

$$F \text{id}_X = \text{id}_{F X}$$
$$F (f \cdot g) = F f \cdot F g$$

For example, forgetful functor $U : \text{CMon} \to \text{Set}$:

$$U (M, \otimes, \epsilon) = M$$
$$U (h : (M, \otimes, \epsilon) \to (M', \oplus, \epsilon')) = h : M \to M'$$

Conversely, Free : $\text{Set} \to \text{CMon}$ generates the free commutative monoid (i.e., bags) on a set of elements:

$$\text{Free} A = (\text{Bag} A, \cup, \emptyset)$$
$$\text{Free} (f : A \to B) = \text{map} f : \text{Bag} A \to \text{Bag} B$$
6. Adjunctions

Adjunctions are the categorical generalisation of Galois connections.

Given categories $\mathbf{C}, \mathbf{D}$, and functors $L : \mathbf{D} \to \mathbf{C}$ and $R : \mathbf{C} \to \mathbf{D}$, adjunction

\[
\begin{array}{c}
\text{C} \\
\downarrow C \Rightarrow \downarrow D \\
\text{D} \\
\downarrow D \Rightarrow \downarrow C \\
\text{R}
\end{array}
\]

means* $[-] : \mathbf{C}(L X, Y) \cong \mathbf{D}(X, R Y) : [-]$

A familiar example is given by currying:

\[
\begin{array}{c}
\text{Set} \\
\downarrow \cong \downarrow \cong \\
\text{Set} \\
\downarrow \cong \downarrow \cong \\
(-)^P
\end{array}
\]

with $\text{curry} : \mathbf{Set}(X \times P, Y) \cong \mathbf{Set}(X, Y^P) : \text{curry}^\circ$

hence definitions and properties of $\text{apply} = \text{uncurry \hspace{1em} id}_{Y^P} : Y^P \times P \to Y$
7. Products and coproducts

\[
\begin{align*}
\text{Set} & \quad \perp \quad \text{Set}^2 \quad \perp \quad \text{Set} \\
\Delta & \quad \text{+} \quad \Delta \quad \times \\
\end{align*}
\]

with

\[
\begin{align*}
\text{fork} : \text{Set}^2(\Delta A, (B, C)) & \simeq \text{Set}(A, B \times C) : \text{fork}^\circ \\
junc^\circ : \text{Set}(A + B, C) & \simeq \text{Set}^2((A, B), \Delta C) : junc
\end{align*}
\]

hence

\[
\begin{align*}
dup & = \text{fork } \text{id}_{A,A} : \text{Set}(A, A \times A) \\
(fst, snd) & = \text{fork}^\circ \text{id}_{B \times C} : \text{Set}^2(\Delta (B, C), (B, C))
\end{align*}
\]

give tupling and projection. Dually for sums and injections, and generally for any arity—even zero.
8. Free commutative monoids

Adjunctions often capture embedding/projection pairs:

\[
\begin{array}{ccc}
\text{CMon} & \perp & \text{Set} \\
\downarrow \text{Free} & & \uparrow \text{Set} \\
\U & \downarrow \text{U} & \end{array}
\]

with \([-\cdot]\) : CMon(Free \(A, (M, \otimes, \epsilon)\)) \cong Set(A, U (M, \otimes, \epsilon)) : [-]

Unit and counit:

\[
\begin{align*}
single A & = [id_{\text{Free } A}] : A \to U (\text{Free } A) \\
reduce M & = [id_M] : \text{Free } (U M) \to M \quad \text{-- for } M = (M, \otimes, \epsilon)
\end{align*}
\]

whence, for \(h : \text{Free } A \to M\) and \(f : A \to U M = M\),

\[
h = reduce M \cdot \text{Free } f \iff U h \cdot single A = f
\]

ie 1-to-1 correspondence between homomorphisms from the free commutative monoid (bags) and their behaviour on singletons.
9. Aggregation

Aggregations are bag homomorphisms:

<table>
<thead>
<tr>
<th>aggregation</th>
<th>monoid</th>
<th>action on singletons</th>
</tr>
</thead>
<tbody>
<tr>
<td>count</td>
<td>((\mathbb{N}, 0, +))</td>
<td>({a} \rightarrow 1)</td>
</tr>
<tr>
<td>sum</td>
<td>((\mathbb{R}, 0, +))</td>
<td>({a} \rightarrow a)</td>
</tr>
<tr>
<td>max</td>
<td>((\mathbb{Z}, minBound, max))</td>
<td>({a} \rightarrow a)</td>
</tr>
<tr>
<td>min</td>
<td>((\mathbb{Z}, maxBound, min))</td>
<td>({a} \rightarrow a)</td>
</tr>
<tr>
<td>all</td>
<td>((\mathbb{B}, True, \wedge))</td>
<td>({a} \rightarrow a)</td>
</tr>
<tr>
<td>any</td>
<td>((\mathbb{B}, False, \lor))</td>
<td>({a} \rightarrow a)</td>
</tr>
</tbody>
</table>

Selection is a homomorphism, to bags, using action

\[
guard : (A \rightarrow \mathbb{B}) \rightarrow \text{Bag } A \rightarrow \text{Bag } A
\]

\[
guard p a = \text{if } p a \text{ then } \{a\} \text{ else } \emptyset
\]

Laws about selections follow from laws of homomorphisms (and of coproducts, since \(\mathbb{B} = 1 + 1\)).
10. Monads

Bags form a *monad* \((\text{Bag}, \text{union}, \text{single})\) with

\[
\begin{align*}
\text{Bag} &= U \cdot \text{Free} \\
\text{union} &:\text{Bag} (\text{Bag} A) \to \text{Bag} A \\
\text{single} &:\text{A} \to \text{Bag} A
\end{align*}
\]

which justifies the use of comprehension notation \(\{ f \ a \ b \mid a \leftarrow x, b \leftarrow g \ a \}\).

In fact, for any adjunction \(L \dashv R\) between \(C\) and \(D\), we get a monad \((T, \mu, \eta)\) on \(D\), where

\[
\begin{align*}
T &= R \cdot L \\
\mu A &= R [ id_A ] L : T (T A) \to T A \\
\eta A &= [ id_A ] : A \to T A
\end{align*}
\]
11. Maps

Database indexes are essentially maps $\text{Map } K V = V^K$. Maps $(-)^K$ from $K$ form a monad (the Reader monad in Haskell), so arise from an adjunction.

The laws of exponents arise from this adjunction, and from those for products and coproducts:

- $\text{Map } 0 V \cong 1$
- $\text{Map } 1 V \cong V$
- $\text{Map } (K_1 + K_2) V \cong \text{Map } K_1 V \times \text{Map } K_2 V$
- $\text{Map } (K_1 \times K_2) V \cong \text{Map } K_1 (\text{Map } K_2 V)$
- $\text{Map } K 1 \cong 1$
- $\text{Map } K (V_1 \times V_2) \cong \text{Map } K V_1 \times \text{Map } K V_2 : \text{merge}$
12. Indexing

Relations are in 1-to-1 correspondence with set-valued functions:

\[ \text{Rel} \xrightarrow{J} \text{Set} \xleftarrow{E} \]

where \( J \) embeds, and \( E R : A \rightarrow \text{Set} B \) for \( R : A \sim B \).

Moreover, the correspondence remains valid for bags:

\[ \text{index} : \text{Bag} (K \times V) \simeq \text{Map} K (\text{Bag} V) \]

Together, \textit{index} and \textit{merge} give efficient relational joins:

\[ x \ f \bowtie g \ y = \text{flatten} (\text{Map} K \ cp (\text{merge} (\text{groupBy} f \ x, \text{groupBy} g \ y))) \]

\( \text{groupBy} : (V \rightarrow K) \rightarrow \text{Bag} V \rightarrow \text{Map} K (\text{Bag} V) \)

\( \text{flatten} : \text{Map} K (\text{Bag} V) \rightarrow \text{Bag} V \)
13. Pointed sets and finite maps

Model *finite maps* $\text{Map}_*$ not as partial functions, but *total* functions to a *pointed* codomain $(A, a)$, i.e. a set $A$ with a distinguished element $a : A$.

Pointed sets and point-preserving functions form a category $\text{Set}_*$. There is an adjunction to $\text{Set}$, via

\[
\begin{array}{ccc}
\text{Set}_* & \downarrow & \text{Set} \\
\uparrow & \circlearrowright & \downarrow \\
\uparrow & & \uparrow \\
\text{Maybe} & & \text{U} \\
\end{array}
\]

where $\text{Maybe } A \cong 1 + A$ adds a point, and $\text{U} (A, a) = A$ discards it.

In particular, $(\text{Bag } A, \emptyset)$ is a pointed set. Moreover, $\text{Bag } f$ is point-preserving, so we get a functor $\text{Bag}_* : \text{Set} \to \text{Set}_*$.

Indexing remains an isomorphism:

\[
\text{index} : \text{Bag}_* (K \times V) \cong \text{Map}_* K (\text{Bag}_* V)
\]
14. Graded monads

A catch: finite maps aren’t a monad, because

$$\eta a = \lambda k \rightarrow a : A \rightarrow \text{Map } K A$$

in general yields an infinite map.

However, finite maps are a graded monad*: for monoid $$(M, \otimes, \epsilon)$$,

$$\mu X : T_m (T_n X) \rightarrow T_{m \otimes n} X$$

$$\eta X : X \rightarrow T_{\epsilon} X$$

satisfying the usual laws. These too arise from adjunctions*.

We use the monoid $$(\mathbb{K}, \times, 1)$$ of finite key types under product.
15. Conclusions

- *monad comprehensions* for database queries
- structure arising from *adjunctions*
- equivalences from *universal properties*
- fitting in *relational joins*, via indexing
- to do: calculating *query optimisations*

Thanks to EPSRC *Unifying Theories of Generic Programming* for funding.
