Relational Algebra by Way of Adjunctions

Jeremy Gibbons
(joint work with Fritz Henglein, Ralf Hinze, Nicolas Wu)
DBPL, October 2015
1. Summary

- bulk types (sets, bags, lists) are monads
- monads have nice mathematical foundations via adjunctions
- monads support comprehensions
- comprehension syntax provides a query notation
  
  \[
  \left[(customer\cdot name, invoice\cdot amount) \mid 
  \begin{array}{l}
  customer ← customers, \\
  invoice ← invoices, \\
  customer\cdot cid = invoice\cdot customer, \\
  invoice\cdot due ≤ today
  \end{array}
  \right]
  \]

- monad structure explains selection, projection
- less obvious how to explain join
2. Galois connections

Relating monotonic functions between two ordered sets:

\[ (A, \leq) \downarrow \quad \perp \quad (B, \subseteq) \]

means \( f \ b \leq a \iff b \subseteq g \ a \)

For example,

\[ \text{floor} \]

\[ \text{inj} \]

\[ (\mathbb{R}, \leq_{\mathbb{R}}) \downarrow \quad (\mathbb{Z}, \leq_{\mathbb{Z}}) \]

\[ \times k \]

\[ \div k \]

“Change of coordinates” can sometimes simplify reasoning; eg rhs gives 
\( n \times k \leq m \iff n \leq m \div k \), and multiplication is easier to reason about than rounding division.
3. Category theory from ordered sets

A category $\mathbf{C}$ consists of

- a set* $|\mathbf{C}|$ of objects,
- a set* $\mathbf{C}(X, Y)$ of arrows $X \to Y$ for each $X, Y : |\mathbf{C}|$,
- identity arrows $\text{id}_X : X \to X$ for each $X$
- composition $f \cdot g : X \to Z$ of compatible arrows $g : X \to Y$ and $f : Y \to Z$,
- such that composition is associative, with identities as units.

Think of a directed graph, with vertices as objects and paths as arrows.

An ordered set $(A, \leq)$ is a degenerate category, with objects $A$ and a unique arrow $a \to b$ iff $a \leq b$.

\[
\ldots\rightarrow -2 \rightarrow -1 \rightarrow 0 \rightarrow 1 \rightarrow 2 \rightarrow \ldots
\]

Many categorical concepts are generalisations from ordered sets.

*proviso...
4. Concrete categories

Ordered sets are a *concrete category*: roughly,

- the objects are *sets with additional structure*
- the arrows are *structure-preserving mappings*

Many useful categories are of this form.

For example, the category \(\text{CMon}\) has commutative monoids \((M, \otimes, \epsilon)\) as objects, and homomorphisms \(h: (M, \otimes, \epsilon) \to (M', \oplus, \epsilon')\) as arrows:

\[
\begin{align*}
h (m \otimes n) &= h m \oplus h n \\
h \epsilon &= \epsilon'
\end{align*}
\]

Trivially, category \(\text{Set}\) has sets as objects, and total functions as arrows.
5. Functors

Categories are themselves structured objects...

A functor $F : C \to D$ is an operation on both objects and arrows, preserving the structure: $F f : F X \to F Y$ when $f : X \to Y$, and

$$F \ id_X = id_{F X}$$
$$F (f \cdot g) = F f \cdot F g$$

For example, forgetful functor $U : CMon \to Set$:

$$U (M, \otimes, \epsilon) = M$$
$$U (h : (M, \otimes, \epsilon) \to (M', \oplus, \epsilon')) = h : M \to M'$$

Conversely, $Free : Set \to CMon$ generates the free commutative monoid (ie bags) on a set of elements:

$$Free A = (Bag A, \cup, \emptyset)$$
$$Free (f : A \to B) = map f : Bag A \to Bag B$$
6. Adjunctions

Adjunctions are the categorical generalisation of Galois connections. Given categories $C, D$, and functors $L : D \to C$ and $R : C \to D$, adjunction

\[ C \perp D \]

means

\[ [-] : C(L X, Y) \simeq D(X, R Y) : [-] \]

A familiar example is given by currying:

\[ \text{Set} \perp \text{Set} \]

with $\text{curry} : \text{Set}(X \times P, Y) \simeq \text{Set}(X, Y^P) : \text{curry}^\circ$

hence definitions and properties of $\text{apply} = \text{uncurry id}_{Y^P} : Y^P \times P \to Y$
7. Products and coproducts

\[
\begin{array}{ccc}
\text{Set} & + & \text{Set}^2 \\
\text{Set}^2 & \Delta & \text{Set} \\
\Delta & \times & \text{Set}
\end{array}
\]

with

\[
\text{fork} : \text{Set}^2(\Delta A, (B, C)) \cong \text{Set}(A, B \times C) : \text{fork}^\circ \\
\text{junc}^\circ : \text{Set}(A + B, C) \cong \text{Set}^2((A, B), \Delta C) : \text{junc}
\]

hence

\[
dup = \text{fork} \ id_{A,A} : \text{Set}(A, A \times A) \\
(fst, snd) = \text{fork}^\circ \ id_{B \times C} : \text{Set}^2(\Delta(B, C), (B, C))
\]

give tupling and projection. Dually for sums and injections, and generally for any arity—even zero.
8. Free commutative monoids

Adjunctions often capture embedding/projection pairs:

\[
\begin{align*}
\text{CMon} & \quad \perp \quad \text{Set} \\
\downarrow & \quad \quad \downarrow \quad \text{U} \\
\text{Free} & \quad \quad \quad \quad \quad \text{with} \quad [-] : \text{CMon}(\text{Free } A, (M, \otimes, \epsilon)) \\
& \quad \quad \quad \quad \quad \approx \text{Set}(A, \text{U} (M, \otimes, \epsilon)) \quad : [-]
\end{align*}
\]

Unit and counit:

\[
\begin{align*}
\text{single } A & = [id_{\text{Free } A}] : A \to \text{U} (\text{Free } A) \\
\text{reduce } M & = [id_M] : \text{Free} (\text{U } M) \to M \quad \text{-- for } M = (M, \otimes, \epsilon)
\end{align*}
\]

whence, for \( h : \text{Free } A \to M \) and \( f : A \to \text{U } M = M \),

\[
h = \text{reduce } M \cdot \text{Free } f \iff \text{U } h \cdot \text{single } A = f
\]

ie 1-to-1 correspondence between homomorphisms from the free commutative monoid (bags) and their behaviour on singletons.
9. Aggregation

Aggregations are bag homomorphisms:

<table>
<thead>
<tr>
<th>aggregation</th>
<th>monoid</th>
<th>action on singletons</th>
</tr>
</thead>
<tbody>
<tr>
<td>count</td>
<td>$(\mathbb{N}, 0, +)$</td>
<td>${a} \rightarrow 1$</td>
</tr>
<tr>
<td>sum</td>
<td>$(\mathbb{R}, 0, +)$</td>
<td>${a} \rightarrow a$</td>
</tr>
<tr>
<td>max</td>
<td>$(\mathbb{Z}, \minBound, \max)$</td>
<td>${a} \rightarrow a$</td>
</tr>
<tr>
<td>min</td>
<td>$(\mathbb{Z}, \maxBound, \min)$</td>
<td>${a} \rightarrow a$</td>
</tr>
<tr>
<td>all</td>
<td>$(\mathbb{B}, \text{True}, \land)$</td>
<td>${a} \rightarrow a$</td>
</tr>
<tr>
<td>any</td>
<td>$(\mathbb{B}, \text{False}, \lor)$</td>
<td>${a} \rightarrow a$</td>
</tr>
</tbody>
</table>

Selection is a homomorphism, to bags, using action

$$\text{guard} : (A \rightarrow \mathbb{B}) \rightarrow \text{Bag} A \rightarrow \text{Bag} A$$

$$\text{guard } p \ a = \text{if } p \ a \text{ then } \{a\} \text{ else } \emptyset$$

Laws about selections follow from laws of homomorphisms (and of coproducts, since $\mathbb{B} = 1 + 1$).
10. Monads

Bags form a \textit{monad} \((\text{Bag}, \text{union}, \text{single})\) with

\[
\begin{align*}
\text{Bag} & = U \cdot \text{Free} \\
\text{union} & : \text{Bag} (\text{Bag} A) \rightarrow \text{Bag} A \\
\text{single} & : A \rightarrow \text{Bag} A
\end{align*}
\]

which justifies the use of comprehension notation \(\{f \ a \ b \mid a \leftarrow x, b \leftarrow g \ a\}^\downarrow\).

In fact, for any adjunction \(L \dashv R\) between \(\mathbf{C}\) and \(\mathbf{D}\), we get a monad \((T, \mu, \eta)\) on \(\mathbf{D}\), where

\[
\begin{align*}
T & = R \cdot L \\
\mu \ A & = R \ [id_A] \ L : T \ (T \ A) \rightarrow T \ A \\
\eta \ A & = [id_A] : A \rightarrow T \ A
\end{align*}
\]
11. Maps

Database indexes are essentially maps $\text{Map } K V = V^K$. Maps $(-)^K$ from $K$ form a monad (the Reader monad in Haskell), so arise from an adjunction. The laws of exponents arise from this adjunction, and from those for products and coproducts:

- $\text{Map } 0 V \cong 1$
- $\text{Map } 1 V \cong V$
- $\text{Map } (K_1 + K_2) V \cong \text{Map } K_1 V \times \text{Map } K_2 V$
- $\text{Map } (K_1 \times K_2) V \cong \text{Map } K_1 (\text{Map } K_2 V)$
- $\text{Map } K 1 \cong 1$
- $\text{Map } K (V_1 \times V_2) \cong \text{Map } K V_1 \times \text{Map } K V_2 : \text{merge}$
12. Indexing

Relations are in 1-to-1 correspondence with set-valued functions:

\[ \text{Rel} \xrightarrow{J} \text{Set} \xleftarrow{E} \]

where \( J \) embeds, and \( E \) \( R : A \to \text{Set} B \) for \( R : A \sim B \).

Moreover, the correspondence remains valid for bags:

\[
\text{index} : \text{Bag} (K \times V) \simeq \text{Map} K (\text{Bag} V)
\]

Together, \( \text{index} \) and \( \text{merge} \) give efficient relational joins:

\[
x f \Join g y = \text{flatten} (\text{Map} K \ cp (\text{merge} (\text{groupBy} f \ x, \text{groupBy} g \ y)))
\]

\[
\text{groupBy} : (V \to K) \to \text{Bag} V \to \text{Map} K (\text{Bag} V)
\]

\[
\text{flatten} : \text{Map} K (\text{Bag} V) \to \text{Bag} V
\]
13. Pointed sets and finite maps

Model \textit{finite maps} \( \text{Map}_* \) not as partial functions, but \textit{total} functions to a \textit{pointed} codomain \((A, a)\), i.e. a set \( A \) with a distinguished element \( a : A \).

Pointed sets and point-preserving functions form a category \( \text{Set}_* \).

There is an adjunction to \( \text{Set} \), via

\[
\begin{array}{ccc}
\text{Set}_* & & \bot & & \text{Set} \\
\downarrow & & \& & & \downarrow \\
\text{Maybe} & & \text{U} \\
\end{array}
\]

where \( \text{Maybe} A \cong 1 + A \) adds a point, and \( \text{U} (A, a) = A \) discards it.

In particular, \((\text{Bag} A, \emptyset)\) is a pointed set. Moreover, \( \text{Bag} f \) is point-preserving, so we get a functor \( \text{Bag}_* : \text{Set} \to \text{Set}_* \).

Indexing remains an isomorphism:

\[
\text{index} : \text{Bag}_* (K \times V) \cong \text{Map}_* K (\text{Bag}_* V)
\]
14. Graded monads

A catch: finite maps aren’t a monad, because

\[ \eta a = \lambda k \to a : A \to \text{Map } K A \]

in general yields an infinite map.

However, finite maps are a *graded monad*: for monoid \((M, \otimes, \epsilon)\),

\[ \mu X : T_m (T_n X) \to T_{m \otimes n} X \]
\[ \eta X : X \to T_\epsilon X \]

satisfying the usual laws. These too arise from adjunctions*.

We use the monoid \((\mathbb{K}, \times, 1)\) of finite key types under product.
15. Conclusions

- *Monad comprehensions* for database queries
- Structure arising from *adjunctions*
- Equivalences from *universal properties*
- Fitting in *relational joins*, via indexing
- To do: calculating *query optimisations*

Thanks to EPSRC *Unifying Theories of Generic Programming* for funding.
