Relational Algebra by Way of Adjunctions

Jeremy Gibbons
(joint work with Fritz Henglein, Ralf Hinze, Nicolas Wu)
DBPL, October 2015
1. Summary

- bulk types (sets, bags, lists) are *monads*
- monads have nice *mathematical foundations via adjunctions*
- monads support *comprehensions*
- comprehension syntax provides a *query notation*

\[
\begin{align*}
[ \ (customer\ .name, invoice\ .amount) \\
| \ customer & \leftarrow customers, \\
\ & invoice \leftarrow invoices, \\
\ & customer\ .cid = invoice\ .customer, \\
\ & invoice\ .due \leq today ]
\end{align*}
\]

- monad structure explains *selection, projection*
- less obvious how to explain *join*
2. Galois connections

Relating monotonic functions between two ordered sets:

\[ (A, \leq) \perp (B, \sqsubseteq) \]

means \( f b \leq a \iff b \sqsubseteq g a \)

For example,

\[ (\mathbb{R}, \leq_{\mathbb{R}}) \perp (\mathbb{Z}, \leq_{\mathbb{Z}}) \]

\[ (\mathbb{Z}, \leq) \perp (\mathbb{Z}, \leq) \]

“Change of coordinates” can sometimes simplify reasoning; eg rhs gives \( n \times k \leq m \iff n \leq m \div k \), and multiplication is easier to reason about than rounding division.
3. Category theory from ordered sets

A category \( C \) consists of

- a set* \( |C| \) of objects,
- a set* \( C(X, Y) \) of arrows \( X \to Y \) for each \( X, Y : |C| \),
- identity arrows \( \text{id}_X : X \to X \) for each \( X \)
- composition \( f \cdot g : X \to Z \) of compatible arrows \( g : X \to Y \) and \( f : Y \to Z \),
- such that composition is associative, with identities as units.

Think of a directed graph, with vertices as objects and paths as arrows.

An ordered set \((A, \leq)\) is a degenerate category, with objects \( A \) and a unique arrow \( a \to b \) iff \( a \leq b \).

\[ \cdots \rightarrow -2 \rightarrow -1 \rightarrow 0 \rightarrow 1 \rightarrow 2 \rightarrow \cdots \]

Many categorical concepts are generalisations from ordered sets.

*proviso...
4. Concrete categories

Ordered sets are a **concrete category**: roughly,

- the objects are *sets with additional structure*
- the arrows are *structure-preserving mappings*

Many useful categories are of this form.

For example, the category **CMon** has commutative monoids \((M, \otimes, \epsilon)\) as objects, and homomorphisms \(h: (M, \otimes, \epsilon) \rightarrow (M', \oplus, \epsilon')\) as arrows:

\[
\begin{align*}
    h (m \otimes n) &= h m \oplus h n \\
    h \epsilon &= \epsilon'
\end{align*}
\]

Trivially, category **Set** has sets as objects, and total functions as arrows.
5. Functors

Categories are themselves structured objects...

A functor $F : C \to D$ is an operation on both objects and arrows, preserving the structure: $F f : F X \to F Y$ when $f : X \to Y$, and

$$F \ id_X = id_{FX}$$
$$F (f \cdot g) = F f \cdot F g$$

For example, forgetful functor $U : CMon \to Set$:

$$U (M, \otimes, \epsilon) = M$$
$$U (h : (M, \otimes, \epsilon) \to (M', \oplus, \epsilon')) = h : M \to M'$$

Conversely, $Free : Set \to CMon$ generates the free commutative monoid (ie bags) on a set of elements:

$$Free A = (Bag A, \cup, \emptyset)$$
$$Free (f : A \to B) = map f : Bag A \to Bag B$$
6. Adjunctions

Adjunctions are the categorical generalisation of Galois connections.

Given categories \( \mathcal{C}, \mathcal{D} \), and functors \( L : \mathcal{D} \to \mathcal{C} \) and \( R : \mathcal{C} \to \mathcal{D} \), adjunction

\[
\begin{array}{ccc}
\mathcal{C} & \perp & \mathcal{D} \\
\downarrow & & \downarrow \\
\mathcal{D} & \perp & \mathcal{C} \\
\end{array}
\]

means\(^*\) \( [-] : \mathcal{C}(L X, Y) \cong \mathcal{D}(X, R Y) : [-] \)

A familiar example is given by currying:

\[
\begin{array}{ccc}
\text{Set} & \perp & \text{Set} \\
\downarrow & & \downarrow \\
\text{Set} & \perp & \text{Set} \\
\end{array}
\]

with \( \text{curry} : \text{Set}(X \times P, Y) \cong \text{Set}(X, Y^P) : \text{curry}^\circ \)

hence definitions and properties of \( \text{apply} = \text{uncurry id}_{Y^P} : Y^P \times P \to Y \)
7. Products and coproducts

with

\[ \text{fork} : \text{Set}^2(\Delta A, (B, C)) \simeq \text{Set}(A, B \times C) : \text{fork}^\circ \]
\[ \text{junc}^\circ : \text{Set}(A + B, C) \simeq \text{Set}^2((A, B), \Delta C) : \text{junc} \]

hence

\[ \text{dup} = \text{fork} \ id_{A,A} : \text{Set}(A, A \times A) \]
\[ (\text{fst}, \text{snd}) = \text{fork}^\circ \ id_{B \times C} : \text{Set}^2(\Delta (B, C), (B, C)) \]

give tupling and projection. Dually for sums and injections, and generally for any arity—even zero.
8. Free commutative monoids

Adjunctions often capture embedding/projection pairs:

\[
\begin{array}{ccc}
\text{CMon} & \downarrow & \text{Set} \\
\downarrow & & \downarrow \\
\text{Free} & \leftrightarrow & \text{Set}
\end{array}
\]

with \([\cdot] : \text{CMon}(\text{Free } A, (M, \otimes, \epsilon)) \cong \text{Set}(A, U (M, \otimes, \epsilon)) : [\cdot]
\]

Unit and counit:

\[
single A = [id_{\text{Free } A}] : A \rightarrow U (\text{Free } A)
\]

\[
\text{reduce } M = [id_M] : \text{Free } (U M) \rightarrow M \quad \text{-- for } M = (M, \otimes, \epsilon)
\]

whence, for \(h : \text{Free } A \rightarrow M\) and \(f : A \rightarrow U M = M\),

\[
h = \text{reduce } M \cdot \text{Free } f \iff U h \cdot \text{single } A = f
\]

ie 1-to-1 correspondence between homomorphisms from the free commutative monoid (bags) and their behaviour on singletons.
# 9. Aggregation

Aggregations are bag homomorphisms:

<table>
<thead>
<tr>
<th>aggregation</th>
<th>monoid</th>
<th>action on singletons</th>
</tr>
</thead>
<tbody>
<tr>
<td>count</td>
<td>((\mathbb{N}, 0, +))</td>
<td>({a} \rightarrow 1)</td>
</tr>
<tr>
<td>sum</td>
<td>((\mathbb{R}, 0, +))</td>
<td>({a} \rightarrow a)</td>
</tr>
<tr>
<td>max</td>
<td>((\mathbb{Z}, \text{minBound}, \text{max}))</td>
<td>({a} \rightarrow a)</td>
</tr>
<tr>
<td>min</td>
<td>((\mathbb{Z}, \text{maxBound}, \text{min}))</td>
<td>({a} \rightarrow a)</td>
</tr>
<tr>
<td>all</td>
<td>((\mathbb{B}, \text{True}, \land))</td>
<td>({a} \rightarrow a)</td>
</tr>
<tr>
<td>any</td>
<td>((\mathbb{B}, \text{False}, \lor))</td>
<td>({a} \rightarrow a)</td>
</tr>
</tbody>
</table>

Selection is a homomorphism, to bags, using action

\[
guard : (A \rightarrow \mathbb{B}) \rightarrow \text{Bag} A \rightarrow \text{Bag} A
\]

\[
guard p a = \text{if } p a \text{ then } \{a\} \text{ else } \emptyset
\]

Laws about selections follow from laws of homomorphisms
(and of coproducts, since \(\mathbb{B} = 1 + 1\)).
10. Monads

Bags form a *monad* \((\text{Bag}, \text{union}, \text{single})\) with 

\[
\begin{align*}
\text{Bag} & = U \cdot \text{Free} \\
\text{union} & : \text{Bag} (\text{Bag } A) \to \text{Bag } A \\
\text{single} & : A \to \text{Bag } A
\end{align*}
\]

which justifies the use of comprehension notation \(\{ f \ a \ b \mid a \leftarrow x, b \leftarrow g \ a \}\).

In fact, for any adjunction \(L \dashv R\) between \(C\) and \(D\), we get a monad \((T, \mu, \eta)\) on \(D\), where 

\[
\begin{align*}
T & = R \cdot L \\
\mu \ A & = R \ [id_A] \ L : T (T \ A) \to T \ A \\
\eta \ A & = [id_A] : A \to T \ A
\end{align*}
\]
11. Maps

Database indexes are essentially maps $\text{Map } K V = V^K$. Maps $(-)^K$ from $K$ form a monad (the Reader monad in Haskell), so arise from an adjunction. The laws of exponents arise from this adjunction, and from those for products and coproducts:

- $\text{Map } 0 V \simeq 1$
- $\text{Map } 1 V \simeq V$
- $\text{Map } (K_1 + K_2) V \simeq \text{Map } K_1 V \times \text{Map } K_2 V$
- $\text{Map } (K_1 \times K_2) V \simeq \text{Map } K_1 (\text{Map } K_2 V)$
- $\text{Map } K 1 \simeq 1$
- $\text{Map } K (V_1 \times V_2) \simeq \text{Map } K V_1 \times \text{Map } K V_2 : \text{merge}$
12. Indexing

Relations are in 1-to-1 correspondence with set-valued functions:

\[
\text{Rel} \cong \text{Set}
\]

where \( J \) embeds, and \( E R : A \rightarrow \text{Set} B \) for \( R : A \sim B \).

Moreover, the correspondence remains valid for bags:

\[
\text{index} : \text{Bag} (K \times V) \cong \text{Map} K (\text{Bag} V)
\]

Together, \textit{index} and \textit{merge} give efficient relational joins:

\[
x f \bowtie_g y = \text{flatten} (\text{Map} K \ cp (\text{merge} (\text{groupBy} f x, \text{groupBy} g y)))
\]

\[
\text{groupBy} : (V \rightarrow K) \rightarrow \text{Bag} V \rightarrow \text{Map} K (\text{Bag} V)
\]

\[
\text{flatten} : \text{Map} K (\text{Bag} V) \rightarrow \text{Bag} V
\]
13. Pointed sets and finite maps

Model *finite maps* \( \text{Map}_* \) not as partial functions, but *total* functions to a *pointed* codomain \((A, a)\), i.e. a set \(A\) with a distinguished element \(a : A\).

Pointed sets and point-preserving functions form a category \( \text{Set}_* \).

There is an adjunction to \( \text{Set} \), via

\[
\begin{array}{ccc}
\text{Set}_* & & \text{Set} \\
\downarrow & \searrow & \searrow \\
\uparrow & \downarrow & \downarrow \\
\text{Maybe} & \rightarrow & \text{U}
\end{array}
\]

where \( \text{Maybe} \ A \simeq 1 + A \) adds a point, and \( \text{U} (A, a) = A \) discards it.

In particular, \((\text{Bag} A, \emptyset)\) is a pointed set. Moreover, \(\text{Bag} f\) is point-preserving, so we get a functor \(\text{Bag}_* : \text{Set} \to \text{Set}_*\).

Indexing remains an isomorphism:

\[
\text{index} : \text{Bag}_* (K \times V) \simeq \text{Map}_* K (\text{Bag}_* V)
\]
14. Graded monads

A catch: finite maps aren’t a monad, because

$$\eta a = \lambda k \to a : A \to \text{Map } K A$$

in general yields an infinite map.

However, finite maps are a graded monad*: for monoid \((M, \otimes, \epsilon)\),

$$\mu X : T_m (T_n X) \to T_{m \otimes n} X$$
$$\eta X : X \to T_{\epsilon} X$$

satisfying the usual laws. These too arise from adjunctions*.

We use the monoid \((\mathbb{K}, \times, 1)\) of finite key types under product.
15. Conclusions

- *Monad comprehensions* for database queries
- Structure arising from *adjunctions*
- Equivalences from *universal properties*
- Fitting in *relational joins*, via indexing
- To do: calculating *query optimisations*

Thanks to EPSRC *Unifying Theories of Generic Programming* for funding.
