Abstract
Overexploitation is one of the main pressures driving wildlife closer to extinction, yet broad-scale data to evaluate species’ declines are limited. Using African pangolins (Family: Pholidota) as a case study, we demonstrate that collating local-scale data can provide crucial information on regional trends in exploitation of threatened species to inform conservation actions and policy. We estimate that 0.4-2.7 million pangolins are hunted annually in Central African forests. The number of pangolins hunted has increased by ~150% and the proportion of pangolins of all vertebrates hunted increased from 0.04% to 1.83% over the past four decades. However, there were no trends in pangolins observed at markets, suggesting use of alternative supply chains. The price of giant \( (Smutsia gigantea) \) and arboreal \( (Phataginus sp.) \) pangolins in urban markets has increased 5.8 and 2.3 times respectively, mirroring trends in Asian pangolins. Efforts and resources are needed to increase law enforcement and population monitoring, and investigate linkages between subsistence hunting and illegal wildlife trade.
Introduction

Overexploitation is one of the main pressures causing species’ declines and local extinctions (Maxwell et al. 2016; Ducatez & Shine 2017). Currently, broad-scale data on the exploitation of terrestrial wildlife, needed to inform conservation policy and action, are lacking (Joppa et al. 2016). Information on wildlife harvests can be difficult to collect because, at times, hunters and traffickers operate secretly to avoid law enforcement, and may be unwilling to disclose what they have harvested (Keane et al. 2008). Law enforcement and seizures data have been used to quantify exploitation of threatened species; however, these data suffer from detection biases and underestimation (Gavin et al. 2010). Instead, collating local-scale hunting studies may provide more accurate estimates of the number of animals hunted and relevant information to aid conservation efforts, complementing seizures data (Sánchez-Mercado et al. 2016).

Pangolins (Family: Manidae), a group of African and Asian scaly mammals, are considered to be “the most heavily trafficked wild mammal in the world,” and are hunted and traded for food and traditional medicines (Challender et al. 2014). They are also used in rituals, art, and magic among communities across Africa (Soewu & Sodeinde 2015) and Asia (e.g., Mahmood et al. 2012). Despite a long history of exploitation, pangolin populations in Asia have declined dramatically (estimated 90% decline of Chinese pangolin [Manis pentadactyla] since the 1960s; Wu et al. 2004). All four Asian pangolin species are listed as “Critically Endangered” or “Endangered” on the International Union for Conservation of Nature (IUCN) Red List of Threatened Species due to past, present, and predicted population declines driven by growing demand for meat and scales (Challender et al. 2014), and compounded by low reproductive rates (Newton et al. 2008; Challender et al. 2012; Cheng et al. 2017). In addition, commercial trade and international trade of wild-caught pangolins has been banned (CITES 2016).

In comparison to Asian pangolins, less is known about the African species: white-bellied (Phataginus tricuspis), black-bellied (Phataginus tetradactyla), giant ground (Smutsia gigantea), and Temminck’s ground pangolin (Smutsia temminckii). They are currently classified as “Vulnerable” by the IUCN (Pietersen, Waterman et al. 2014; Waterman et al. 2014a,b; Waterman, Pietersen et al. 2014), and international trade was recently banned (CITES 2016). African pangolin populations are assumed to be declining, because of habitat degradation and loss (Challender et al. 2014), hunting, and increasing demand from international markets (Challender & Hywood 2012). However, little is known about population sizes, reproductive potential, and African pangolin trade.

Mounting evidence suggests that as the availability of Asian pangolins declines and international trade flows increase, traders are increasingly supplying the currently more abundant and less expensive African pangolins to meet Asian demand (Challender & Hywood 2012).

Seizures of pangolins and their derivatives (e.g., scales and skins) from Africa destined for Asia are increasing (Heinrich et al. 2016) with over 53 tons seized in 2013 (Flocken 2015), and more than 1 million pangolins trafficked globally since 2000 as estimated from illegal trade data (IUCN SSC Pangolin Specialist Group 2016). These estimates likely represent a fraction of all pangolins traded, and an even smaller proportion of the number of pangolins hunted.

Many studies have monitored wildlife hunting and/or markets at local scales across Africa (e.g., Crookes et al. 2006; Coad et al. 2013). Collating data from these studies allows us to infer trends, produce indicators of overall rarity and demand at a regional scale, and provide information to aid conservation efforts. Here, we collate data from local-scale hunting and market studies to provide the first comprehensive assessment of the exploitation of African pangolins by estimating: (1) the total number of pangolins hunted annually; (2) temporal trends in the proportion of pangolins of all animals hunted or observed at wild meat markets; and (3) trends in the price of pangolins over time as an indicator of changes in demand or rarity (Courchamp et al. 2006).

Materials and methods

Data

We collated data on the number of individual vertebrates hunted or observed at wild meat markets in a particular area and time period across Africa from a variety of “sources” (published papers, reports from nongovernmental organizations, PhD or Master’s theses, or unpublished data collected using a published methodology) using a snowballing technique (Noy 2008), and searching reference lists and online libraries. Where sources did not provide detailed data on animals hunted or observed at markets, we contacted the authors for raw data. Where available, we extracted information on use (e.g., consumed, sold), hunting method (e.g., gun, snare), sex, age category (as assessed by the authors), and price of whole animals observed at markets.

Each source could contain one or more “studies,” where each “study” collected data using a specific sampling methodology at a location, and was assigned a unique StudyID. Each study provided data on the location (hereafter “site”), market type (urban or rural), start and end date, species and number of individuals hunted.
Assessing African pangolin exploitation

Thryonomys swinderianus
Philantomba monticola
Atherurus africanus

To investigate trends over time, we allocated data from studies to the years in which the data were collected. Studies spanning multiple years, including studies of less than a year’s duration, were separated into annual “samples” if temporally resolved raw data were available and could be separated and allocated to a year (n = 16 studies). Studies that provided temporally unresolved data, i.e., one value per species for the entire study duration, were included if the study duration was ≤500 days to allow reasonable allocation of data to individual years, while including studies that sampled slightly longer than 1 year. All samples were allocated to a year by calculating the mid-date between the start and end dates.

Estimating total catch of pangolins in Central African forests

Most studies that have human population and hunting territory size data available were located in Central African forests; we therefore restricted the estimates of total pangolin catch to this region. We define Central African forests as the forests in Cameroon, Central African Republic, Equatorial Guinea, Gabon, Democratic Republic of Congo, and Republic of Congo. We used three methods to estimate the total annual catch of pangolins in Central African forests from hunting studies. For the first method, we calculated the median annual number of pangolins hunted per area multiplied by the total likely hunted forest area, calculated as the forest area within 10 km of a settlement (Text S1). For the other two methods, we calculated the median annual number of pangolins hunted per rural person multiplied by either of two independent estimates of the total rural population (CIESIN et al. 2011; UNPD 2014; see Text S1 and Figure S1). To assess change over time, we repeated the analyses for samples collected before and after 2000 (Text S2), to permit comparison with Heinrich et al. (2016) showing an increase in seizures of African pangolins destined for Asia after 2000.

Trends in pangolins hunted and observed at market

To investigate trends of pangolins hunted or observed at markets, we calculated the percentage of individuals from all African pangolin species combined among the total number of vertebrates in the catch or at markets within each sample, from hunting or market studies, respectively. We fitted linear mixed effects models (Zuur et al. 2009) using the lme4 package (Bates et al. 2015) in R version 3.2.4 (R Core Team 2016), and selected the final model using backward model simplification based on likelihood ratio tests. Arcsine-transformed percentages of pangolins in the catch or at markets were modeled separately as the response variable (Andreano et al. 2015), with year and a second-order polynomial of year as fixed effects. As random factors we included StudyID nested within SourceID to control for some of the variation due to research methods and site, and Country to account for variation among countries. Within the statistical models, the percentages of pangolins were weighted by the total number of animals within each sample as a proxy for sample size. Furthermore, we assessed overall trends that may influence our results (such as body mass, accessibility, and sample duration, see Text S3, Text S4), and assessed whether the inclusion of the small number of early studies affected overall trends (Text S5).

Trends in prices

To investigate trends in prices of whole pangolin carcasses at markets, we adjusted all prices in Central African Francs (CFA) to 2015 prices by controlling for inflation using the consumer price index (CPI; The World Bank 2017). We fitted mixed effects models for arboreal and giant ground pangolins with log-transformed price as the response variable, interaction of year and market type (rural or urban) as a fixed effect, and SourceID as a random effect to control for some of the variation due to research methods and site. StudyID was not needed in these analyses because studies were not different from sources.

Separately, we calculated the price ratios of pangolins (averaged when multiple prices were reported per site and source) relative to three commonly hunted and similarly sized species using unadjusted prices, to control for changes in prices of traded vertebrates. We calculated price ratios for blue duiker (Philantomba monticola), African brush-tailed porcupine (Atherurus africanus), and greater cane rat (Thryonomys swinderianus), using fresh carcass prices where specified. We investigated price ratio trends for arboreal pangolins (Phataginus sp.) as insufficient price data were available for ground pangolins (Smutsia sp.). Mixed effects models were fitted for each of the prices ratios as described above.
Assessing African pangolin exploitation

D. J. Ingram et al.

Results

Data

We collated data from 68 sources that met our inclusion criteria (Table S1), separated into 161 studies and 204 samples, accounting for 348,807 individual vertebrates. Of these, 152 samples had information on 71,716 individual vertebrates in the catch and 52 samples investigated 277,091 individuals at markets, of which 2,059 and 7,005 individuals were pangolins, respectively. Across all samples, 8,166 individuals were identified as arboreal pangolins (Phataginus spp.) and 300 as ground pangolins (Smutsia spp.), with a further 578 only identified to family (Manidae).

Pangolins were hunted at 71 of 113 (63%) sites in 10 of 14 (71%) countries, and observed at 18 of 36 (50%) markets in all seven countries for which we have data (Figure 1). On average, over time and across countries, per sample, pangolins represented 2.1 ± 0.27% (mean ± SE) of vertebrates in the catch and 1.4 ± 0.23% at markets.

The sex composition of pangolins in the catch was 49% female, 45% male, with 6% of unknown sex ($n = 560$ pangolins from 10 sources). Most (50%) were adults, 45% juveniles and subadults, and 5% of unknown age ($n = 310$ pangolins, 5 sources). Pangolins were hunted by traps and snares (54%), hand (25%), gun (16%), or other means (5%) ($n = 822$ pangolins, 14 sources). Pangolins were either directly consumed (50%), sold (41%), or given as gifts (9%) ($n = 425$ pangolins, 9 sources).

Estimating total catch of pangolins in Central African forests

We estimate that between 0.42 and 2.71 million pangolins (Phataginus spp. and S. gigantea) were hunted each year in Central Africa (sampled range 1975-2014), with the two human population-based methods giving higher estimates of 1.68 million (0.22-4.76 interquartile range) and 2.71 million (0.35-7.66) pangolins (Figure 2; Table S1 and Figure S2). The total annual catch of pangolins has increased by an estimated 145-151% from before 2000 (range 1975-1999) to post-2000 (2000-2014) depending on estimation method (Figure 2).

S. temminckii does not occur in Central African forests, and insufficient data were available to estimate total annual catch where it occurs.

Trends in pangolins hunted and observed at markets

The percentage of pangolins in the catch increased significantly from 0.04% in 1972 to 1.83% in 2014 (Figure 3A, minimum adequate model: percentage of
pangolins = year + random effects of StudyID nested within SourceID, and Country, $\chi^2_{5,6} = 6.4, P = 0.012$).

For comparison, we also found no temporal trends for the main hunted taxonomic groups (Cetartiodacyla and Rodentia; Figure S3), but we did find that pangolins account for more of the catch in the most accessible areas (Figure S4). The percentage of pangolins observed at markets did not change significantly between 1975 and 2010 (Figure 3B; $\chi^2_{4,5} = 1.9, P = 0.17$).

**Trends in price**

We collated price data for arboreal ($n = 149$ records) and giant ground ($n = 32$) pangolins from 31 sources in five countries. Prices for arboreal pangolins changed significantly over time, and changes differed depending on market type (Figure 4A, interaction: $\chi^2_{6,8} = 8.0, P = 0.02$; urban markets increasing from $\sim3,700$ to $8,500$ Central African Francs [CFA] and rural markets decreasing slightly from $3,200$ to $2,700$ CFA). The price of giant ground pangolins increased significantly at urban markets between 1993 and 2014 from approximately $24,000$ to $140,000$ CFA (Figure 4B: $\chi^2_{3,4} = 3.9, P = 0.05$), but not in rural ones where we have few prices ($n = 8$).

We calculated price ratios for blue duikers ($n = 134$ price records), brush-tailed porcupines ($n = 134$), and cane rats ($n = 82$) based on data from 31 sources collected at 85 sites in five countries between 1992 and 2014 (Table S1). Price ratios of arboreal pangolins to blue duikers increased significantly in urban markets ($0.024 \pm 0.008$ ratio increase per year $\pm$ SE, Figure 5A, Figure S5), and decreased in rural markets ($-0.017 \pm 0.007$ ratio decrease per year; interaction of year and market type, $\chi^2_{5,6} = 12.9, P = 0.0003$). We found no significant interaction...
of year and market type for the price ratio with porcupines ($\chi^2_{3,6} = 3.0, P = 0.08$) or cane rats ($\chi^2_{3,6} = 0.06, P = 0.81$), or any effect of year on the price ratios for porcupines ($\chi^2_{3,4} = 0.03, P = 0.87$) or cane rats ($\chi^2_{3,4} = 0.01, P = 0.93$).

**Discussion**

By collating local-scale studies, we provide the first regional estimates of African pangolin exploitation, revealing that pangolins are hunted and observed at markets throughout West and Central Africa, and that pressure from hunting has increased. The proportion of pangolins in the catch increased significantly over time, while the proportion observed at markets remained unchanged. We found evidence that the price of whole pangolins increased significantly at urban markets, but not at rural ones.

We estimate that 0.4-2.7 million pangolins (P. tricuspis, P. tetradactyla, and S. gigantea) were hunted annually in Central African forests, based on forest area- or human population-based extrapolations of average hunting levels. Our area-based estimate of ~420,000 pangolins hunted annually is consistent with a previous area-based estimate of ~400,000 P. tricuspis, and ~100,000 S. gigantea annually in Central Africa, although based on fewer studies and excluding P. tetradactyla (Fa & Peres 2001). Studies rely on the willingness of hunters to participate, so studies may represent only a subset of hunters at a particular site. Furthermore, hunters and traders may either fail to report illegally hunted protected species, or may not participate in studies; therefore, our extrapolations are likely conservative.

Our analyses suggest that the number of pangolins hunted has increased. Comparing forest area- or population-based extrapolations of data from before and after 2000, we found an ~150% increase, although interquartile ranges overlap likely due to relatively small sample sizes. When analyzing hunting samples, the percentage of pangolins out of the total catch increased significantly from ~0% to ~2% over four decades. The percentage of pangolins observed at markets remained unchanged, suggesting pangolins may be traded along alternative supply chains as observed in Ghana where pangolins were often traded to wholesalers away from wild meat markets (Boakye et al. 2016), and in Gabon where Asian industry workers buy pangolins directly from hunters (Mambeya et al. unpublished). The reliability of market studies to assess exploitation has been questioned (Crookes et al. 2006) because individuals observed at markets likely represent a fraction of those hunted as traders hide illegal goods to avoid law enforcement. We cannot discern whether the observed increase in pangolins hunted is caused by: (1) increased consumption, (2) increased hunting of smaller mammals due to declines in larger species (Ingram et al. 2015), (3) changes in hunting technology, and/or (4) increased demand from international markets (Challender & Hywood 2012).

We provide evidence that current hunting of African pangolins is likely unsustainable. On average, 45% of individuals were either juveniles or subadults, an indicator of overexploitation (Weinbaum et al. 2013), although aging subadults is difficult and our assessment relies on the authors reporting of age. This is of concern because pangolins take up to 2 years to reach sexual maturity and produce only one pup annually (Soewu & Sodeinde 2015), suggesting many of the pangolins hunted had not reproduced. Traps and snares were the most common hunting method (54%), however, the use of wire snares is illegal in all pangolin range states because they are effectively “blind” to the species trapped, but law enforcers often ignore or tolerate snaring (LAGA 2015). Effective law enforcement is needed, and should include stricter controls of snaring, such as snare specialist teams (Gandiwa et al. 2013), the elimination of corruption, and the provision of alternative protein sources and incomes.

We found substantial price increases for giant ground pangolins at urban markets, which may suggest that early signs of increased demand may not yet have been passed down to rural hunters, or that prices are responding to increased demand that is unmet by hunters because of depletion. We found small increases in prices and price ratios for arboreal pangolins in urban markets that, while increasing slowly, appear to be following the increasing trend of prices in Asia (Newton et al. 2008). Anecdotal evidence suggests that rural hunters may not yet know the value of pangolins elsewhere (Mambeya et al. unpublished).

While CITES provides a mandate for sustainable international wildlife trade, recently banning trade of all pangolin species (CITES 2016), it does not provide enforcement mechanisms on the ground. To implement the trade ban, governments, law enforcement officials, and conservationists need to better understand the supply chains of pangolins from Africa and Asia, to implement an appropriate monitoring program, and to increase the capacity to enforce the ban and intercept illegal shipments. To better target and inform conservation efforts, tailored survey methods to accurately estimate pangolin abundance and collect vital ecological data are needed. In addition, efforts should focus on determining local demand, and when/where this leads to unsustainable hunting. For cases where pangolin hunting is unsustainable, efforts should be made to improve and increase domestic law enforcement, increase public
Understanding African pangolin exploitation

Human Ecol. et al. 1 Biometrical J. 44 2017 The Authors. Conservation Letters published by
Global rural-urban mapping project, version 1 (2011) in Central Africa (Cameroon, Cen-
tral African Republic, Equatorial Guinea, Gabon, Democratic Republic of Congo, Republic of Congo) classified
into groups by standard deviation, and clipped by forest
cover. Together, these types of data give insights into dif-
ferent aspects of pangolin use and trade, and paint a more
complete picture of pangolin exploitation. In the absence
of continent-wide species monitoring programs, collat-
ing local-scale data can highlight pressures on wildlife, and
provide detailed quantitative information on wildlife ex-
loitation that are crucial to inform conservation action
and policy.
