ABSTRACT

We derive a general formula for the Euler characteristic of a fibration of projective hypersurfaces in terms of invariants of an arbitrary base variety. When the general fiber is an elliptic curve, such formulas have appeared in the physics literature in the context of calculating D-brane charge for M-/F-theory and type-IIB compactifications of string vacua. While there are various methods for computing Euler characteristics of algebraic varieties, we prove a base-independent pushforward formula which reduces the computation of the Euler characteristic of relative hypersurfaces to simple algebraic manipulations of rational expressions determined by its divisor class in a projective bundle. We illustrate our methods by applying them to an explicit family of relative hypersurfaces whose fibers are of arbitrary dimension and degree.

I. INTRODUCTION

Viewing algebraic geometry from a relative perspective has played a crucial role in its modern development. From such a viewpoint, the fundamental objects are morphisms between varieties, and the static objects of classical algebraic geometry are associated with morphisms to a point. In particular, given an equation defining a classical projective variety, such as

\[ y^2z = x^3 + fxz^2 + gz^3, \quad f, g \in \mathbb{C}, \quad (1.1) \]

the relative viewpoint sees the numbers \( f \) and \( g \) as sections of line bundles over a point so that we may promote the status of Eq. (1.1) to relative algebraic geometry by viewing \( f \) and \( g \) as sections of line bundles over an arbitrary smooth base variety. As such, we may view Eq. (1.1) as an equation for a hypersurface not necessarily in \( \mathbb{P}^2 \) but in a \( \mathbb{P}^2 \)-bundle over a smooth base variety \( X \), giving rise to an elliptic fibration \( Y_X \to X \), where the fiber over a point \( p \in X \) is given by

\[ y^2z = x^3 + f(p)xz^2 + g(p)z^3. \]

As this construction makes no use of any particular features of the base variety \( X \), we may view Eq. (1.1) as a map which takes a smooth variety \( X \) to the elliptic fibration \( Y_X \to X \). Just as the fibration \( Y_X \) is determined by \( X \), certain invariants of \( Y_X \) are determined by a combination of invariants of \( X \) and invariants of the line bundles for which \( f \) and \( g \) are sections of. For example, the Euler characteristic of \( Y_X \)—which is the fundamental dimensionless quantity associated with any space—will always be a certain \( \mathbb{Z} \)-linear combination of products of Chern classes of \( X \) with the first Chern class of a line bundle \( L \to X \).

The purpose of this note is to compute formulas for the Euler characteristic for relative hypersurfaces such as \( Y_X \) solely in terms of invariants of an arbitrary smooth base variety \( X \). Such formulas are sometimes called “Sethi-Vafa-Witten” formulas \cite{1,2,6,8} since if \( X \) is a Fano threefold, one may construct \( Y_X \to X \) such that the total space \( Y_X \) is a Calabi-Yau elliptic fourfold for which Sethi, Vafa, and Witten—who
were motivated by constructing supersymmetric compactifications of M- and F-theory [Ref. 14, Formula (2.12)]—derived a formula for the Euler characteristic of $Y_X$ in terms of the Chern classes of $X$, namely,

$$\chi(Y_X) = \int_X 12c_1(X)c_2(X) + 360c_1(X)^3. \quad (1.2)$$

While the RHS of formula (1.2) depends on the fact that in this particular case, $X$ is of dimension 3, Aluffi and Esole showed one can compute a formula for the Euler characteristic for the relative variety $Y_X$ for all possible $X$ at once (Ref. 1, Corollary 4.3), yielding the formula

$$\chi(Y_X) = \int_X 12c_1(X) \sum_{i=0}^{\dim(X)-1} c_i(X)(-6c_1(X))^{i+\dim(X)-i-1}. \quad (1.3)$$

In this paper our focus is to derive a generalization of (1.3) for the case where the fiber is not necessarily an elliptic curve but rather a general projective hypersurface of arbitrary degree and dimension.

Along with providing a general procedure for obtaining such formulas for the Euler characteristic of relative varieties such as $Y_X$, we show that such Euler characteristic formulas actually contain the information of the total Chern class of the relative variety pushed forward to the base. In regard to the elliptic fibration $Y_X$, if we denote the projection of $Y_X$ to $X$ by $\varphi: Y_X \to X$, we show (as a consequence of Theorem 6.1)

$$\varphi_\ast c(Y_X) = \sum_{j=1}^{\dim(X)} \left(12c_1(X) \sum_{i=0}^{j-1} c_i(X)(-6c_1(X))^{i+1-j-i}\right), \quad (1.4)$$

where $\varphi_\ast c(Y_X)$ denotes the proper pushforward to $X$ of the total Chern class of $Y_X$. The index $j$ in formula (1.4) then corresponds to the component of $\varphi_\ast c(Y_X)$ of codimension $j$ in $X$ so that all components of $\varphi_\ast c(Y_X)$ are essentially truncations of the Euler characteristic formula (1.3). Moreover, in keeping with the relative perspective, there is a functorial theory of Chern classes for which $\varphi_\ast c(Y_X)$ is precisely the Chern class of the morphism $\varphi: Y_X \to X$.

Our approach to Chern classes is rooted in Fulton-MacPherson intersection theory so that the Chern class of a variety is taken to be the pushforward of the tautological line bundle corresponding to the fiberwise component of $X$. The index $j$ in formula (1.4) then corresponds to the component of $\varphi_\ast c(Y_X)$ of codimension $j$ in $X$ so that all components of $\varphi_\ast c(Y_X)$ are essentially truncations of the Euler characteristic formula (1.3). Moreover, in keeping with the relative perspective, there is a functorial theory of Chern classes for which $\varphi_\ast c(Y_X)$ is precisely the Chern class of the morphism $\varphi: Y_X \to X$.

Our approach to Chern classes is rooted in Fulton-MacPherson intersection theory so that the Chern class of a variety is taken to be the pushforward of the tautological line bundle corresponding to the fiberwise component of $X$. The index $j$ in formula (1.4) then corresponds to the component of $\varphi_\ast c(Y_X)$ of codimension $j$ in $X$ so that all components of $\varphi_\ast c(Y_X)$ are essentially truncations of the Euler characteristic formula (1.3). Moreover, in keeping with the relative perspective, there is a functorial theory of Chern classes for which $\varphi_\ast c(Y_X)$ is precisely the Chern class of the morphism $\varphi: Y_X \to X$.

Our approach to Chern classes is rooted in Fulton-MacPherson intersection theory so that the Chern class of a variety is taken to be the pushforward of the tautological line bundle corresponding to the fiberwise component of $X$. The index $j$ in formula (1.4) then corresponds to the component of $\varphi_\ast c(Y_X)$ of codimension $j$ in $X$ so that all components of $\varphi_\ast c(Y_X)$ are essentially truncations of the Euler characteristic formula (1.3). Moreover, in keeping with the relative perspective, there is a functorial theory of Chern classes for which $\varphi_\ast c(Y_X)$ is precisely the Chern class of the morphism $\varphi: Y_X \to X$.

The paper is organized as follows. In Sec. II, we illustrate a general procedure for embedding relative projective varieties in a projective bundle by constructing a relative hypersurface which we prove in Sec. IV. Our formula is essentially a generalization to projective bundles of the pushforward formula proved in Sec. IV to bypass the singularity-theoretic methods used in Sec. V and compute the Chern class of the relative variety pushed forward to the base. In regard to the elliptic fibration $Y_X$, if we denote the projection of $Y_X$ to $X$ by $\varphi: Y_X \to X$, we show (as a consequence of Theorem 6.1)

$$\varphi_\ast c(Y_X) = \sum_{j=1}^{\dim(X)} \left(12c_1(X) \sum_{i=0}^{j-1} c_i(X)(-6c_1(X))^{i+1-j-i}\right), \quad (1.4)$$

where $\varphi_\ast c(Y_X)$ denotes the proper pushforward to $X$ of the total Chern class of $Y_X$. The index $j$ in formula (1.4) then corresponds to the component of $\varphi_\ast c(Y_X)$ of codimension $j$ in $X$ so that all components of $\varphi_\ast c(Y_X)$ are essentially truncations of the Euler characteristic formula (1.3). Moreover, in keeping with the relative perspective, there is a functorial theory of Chern classes for which $\varphi_\ast c(Y_X)$ is precisely the Chern class of the morphism $\varphi: Y_X \to X$.

Our approach to Chern classes is rooted in Fulton-MacPherson intersection theory so that the Chern class of a variety is taken to be the pushforward of the tautological line bundle corresponding to the fiberwise component of $X$. The index $j$ in formula (1.4) then corresponds to the component of $\varphi_\ast c(Y_X)$ of codimension $j$ in $X$ so that all components of $\varphi_\ast c(Y_X)$ are essentially truncations of the Euler characteristic formula (1.3). Moreover, in keeping with the relative perspective, there is a functorial theory of Chern classes for which $\varphi_\ast c(Y_X)$ is precisely the Chern class of the morphism $\varphi: Y_X \to X$.

The paper is organized as follows. In Sec. II, we illustrate a general procedure for embedding relative projective varieties in a projective bundle by constructing a relative hypersurface $Z_X(n, d) \to X$ of degree $d$ in a $\mathbb{P}^d$-bundle (for arbitrary integers $d \geq 2$ and $n \geq 1$), for which $Z_X(2, 3)$ may serve as an $F$-theory compactification of string vacua which has yet to appear in the literature. In Sec. III, we review the theory of Chern classes from a functorial perspective and how it lends itself to a natural extension of the Gauss-Bonnet-Chern theorem to the relative setting. The pushforward formula is then proved in Sec. IV. In Sec. V, we define the Chern class of a morphism and then use the functorial formalism introduced in Sec. III to compute the Chern class of the morphism $Z_X(n, d) \to X$ constructed in Sec. II. While the aforementioned Chern class computation in Sec. V relies on the contribution of singular fibers of $Z_X(n, d) \to X$ and singular Chern classes, in Sec. VI, we apply the pushforward formula proved in Sec. IV to bypass the singularity-theoretic methods used in Sec. V and compute the Chern class of the morphism associated with an arbitrary relative hypersurface in a $\mathbb{P}^d$-bundle via simple algebraic manipulations, yielding Sethi-Vafa-Witten formulas analogous to (1.3).

For the rest of the paper, we work over the complex numbers $\mathbb{C}$ although pretty much everything we do work over an arbitrary algebraically closed field of characteristic zero.

II. CONSTRUCTING A RELATIVE VARIETY

As varieties are typically embedded in either affine or projective space, relative varieties are typically embedded in either relative affine or projective spaces, which are vector bundles and projective bundles (respectively) over a smooth base variety. For the sake of compactness, we will restrict ourselves to the projective case so that our relative varieties will be embedded in projective bundles over a smooth compact base variety. One may construct projective bundles either as the space of fiberwise lines or fiberwise hyperplanes passing through the zero-section of a vector bundle. In what follows, we will choose the former alternative.

Let $X$ be a smooth compact variety over $\mathbb{C}$. For every complex vector bundle $\mathcal{E} \to X$ of rank $n + 1$, we let $\mathbb{P}(\mathcal{E}) \to X$ denote the projective bundle of lines in $\mathcal{E}$, which is a $\mathbb{P}^n$-bundle over $X$. The projective bundle comes with a tautological line bundle corresponding to the fiberwise lines in $\mathcal{E}$ which we denote by $\mathcal{O}(-1)$. We then denote its dual by $\mathcal{O}(1)$, whose restriction to each $\mathbb{P}^n$ fiber of $\mathbb{P}(\mathcal{E}) \to X$ is the line bundle associated with a hyperplane. Given a homogeneous equation in $n + 1$ variables which defines a hypersurface in $\mathbb{P}^n$, we may promote its numerical coefficients to sections of line bundles over $X$ in such a way that the homogeneous equation defines a hypersurface $Y_X \hookrightarrow \mathbb{P}(\mathcal{E})$ in a projective bundle $\mathbb{P}(\mathcal{E}) \to X$. In such a case, we refer to $Y_X$ as a projecto-relative hypersurface.
For the remainder of this section, let \( d \geq 2 \) and \( n \geq 1 \) be arbitrary integers. We now construct an example of a projecto-relative hypersurface of arbitrary degree in a \( \mathbb{P}^n \)-bundle \( \mathbb{P}(\mathcal{E}) \to X \) (the vector bundle \( \mathcal{E} \) will be determined by our construction). For this, we use the equation

\[
x_1^d + \cdots + x_n^d + f x_1 x_{d-1}^n + g x_0^d = 0. \tag{2.1}
\]

When \( f \) and \( g \) are complex numbers, Eq. (2.1) defines a smooth hypersurface of degree \( d \) in \( \mathbb{P}^n \) whenever

\[
(d-1)^{d-1} f^d + d(-d)^{d-1} g^{d-1} \neq 0,
\]

and a singular hypersurface whenever

\[
(d-1)^{d-1} f^d + d(-d)^{d-1} g^{d-1} = 0.
\]

A projecto-relative hypersurface associated with Eq. (2.1) then enables us to bring together smooth and singular manifestations of Eq. (2.1) into a single family. In particular, the homogeneous coordinates \( x_0, x_1, \ldots, x_n \) of \( \mathbb{P}^n \) will now be homogeneous coordinates in the fibers of a \( \mathbb{P}^n \)-bundle \( \pi : \mathbb{P}(\mathcal{E}) \to X \). Each \( x_i \) will then be a section of \( \mathcal{O}(1) \otimes \pi^* \mathcal{L}_i \), where \( \mathcal{L}_i \to X \) is an ample line bundle on \( X \) which keeps track of how the coordinate \( x_i \) twists from fiber to fiber in \( \pi : \mathbb{P}(\mathcal{E}) \to X \). And for Eq. (2.1) to give a well defined zero-locus of a section of a line bundle on \( \mathbb{P}(\mathcal{E}) \), each monomial on the LHS of Eq. (2.1) must be a section of the same line bundle. Since for example, \( x_1^d \) is a section of \( \mathcal{O}(d) \otimes \mathcal{L}_1 \), we take \( \mathcal{L} = \mathcal{L}_i \) for some fixed ample line bundle \( \mathcal{L} \to X \) for \( i = 1, \ldots, n \). Now after taking \( x_0 \) to be a section of \( \mathcal{O}(1) \) and \( f \) and \( g \) to be sections of \( \pi^* \mathcal{L}_1^{-1} \) and \( \pi^* \mathcal{L}_d \), respectively, every monomial of (2.1) is then a well-defined section of \( \mathcal{O}(d) \otimes \pi^* \mathcal{L}_1^{-1} \). The aforementioned prescriptions are then consistent with \( \mathcal{E} \to X \) being given by

\[
\mathcal{E} = \mathcal{O} \oplus \bigoplus_{i=1}^n \mathcal{L}_i
\]

(so that each \( x_i \) corresponds to a summand of \( \mathcal{E} \)). Equation (2.1) then defines a projecto-relative hypersurface \( Z_X(n,d) \to \mathbb{P}(\mathcal{E}) \), and composing the embedding with the bundle projection \( \pi : \mathbb{P}(\mathcal{E}) \to X \) yields an associated projection morphism \( \varphi : Z_X(n,d) \to X \), whose fibers are degree \( d \) hypersurfaces in \( \mathbb{P}^n \). The singular fibers of \( \varphi : Z_X(n,d) \to X \) lie over the (singular) hypersurface

\[
\Delta_d : ((d-1)^{d-1} f^d + d(-d)^{d-1} g^{d-1} = 0) \subset X.
\]

To ensure that the total space of the relative variety \( Z_X(n,d) \) is smooth, we must assume that the hypersurfaces \( \{ f = 0 \} \) and \( \{ g = 0 \} \) are smooth and intersect transversally. We note that a general fiber of \( Z_X(n,d) \) is Fano for \( d < n + 1 \), Calabi-Yau for \( d = n + 1 \), and of general type for \( d > n + 1 \).

To construct relative varieties defined by more than one equation, the procedure is more or less the same. Often times however, one has to use more than a single line bundle to tensor the projective coordinates with. An explicit example of a relative complete intersection was constructed in Ref. 6.

**Remark 2.1.** The fibration \( Z_X(2,3) \to X \) is an elliptic fibration given by

\[
Z_X(2,3) : (x^3 + y^3 + f x z^2 + g z^3 = 0) \subset \mathbb{P}(\mathcal{O} \oplus \mathcal{L} \oplus \mathcal{O}),
\]

whose discriminant is given by

\[
\Delta : (4f^3 + 27g^2 = 0) \subset X.
\]

If \( X \) is Fano and \( \mathcal{L} = \mathcal{O}(-K_X) \), \( Z_X(2,3) \) has vanishing first Chern class; thus, in such a case, \( Z_X(2,3) \) is in fact Calabi-Yau. As such, \( Z_X(2,3) \) then serves as a natural compactification of \( F \)-theory which may be viewed as a specialization of the \( E_8 \) fibration defined in Ref. 2. However, \( Z_X(2,3) \) has a much simpler singular fiber structure than \( E_8 \) fibrations as its general singular fiber over \( \Delta \) is a cuspidal cubic, which enhances over \( \{ f = g = 0 \} \subset \Delta \) to a bouquet of 3 \( \mathbb{P}^1 \)'s meeting at a point. Moreover, all smooth fibers of \( Z_X(2,3) \) have \( j \)-invariant 0, which makes \( Z_X(2,3) \) a very special case of the \( E_8 \) family.

**III. Functorial Chern Classes**

In the 1970s, MacPherson constructed a natural transformation of covariant functors which yields a functorial theory of Chern classes for (possibly singular) varieties.\textsuperscript{15} In particular, let \( F \) denote the constructible function functor which takes a variety \( X \) to its group of constructible functions
Given a proper morphism \( f: X \to Y \) and a constructible function \( 1_W \) for some closed subvariety \( W \subset X \), its pushforward \( f_*1_W \) is the constructible function on \( Y \) given by

\[
  f_*1_W(p) = \chi(f^{-1}(p) \cap W),
\]

where \( \chi : \text{Var}_C \to \mathbb{Z} \) denotes the map which takes a complex variety to its topological Euler characteristic with compact support. This definition then extends to arbitrary constructible functions by linearity. If \( \dim(W) = \dim(f(W)) \), the field of rational functions on \( f(W) \) is a finite extension of the field of rational functions on \( W \), whose degree we denote by \( k \). The proper pushforward of the rational equivalence class \( [W] \in A_*X \) is then given by

\[
  f_*[W] = \begin{cases} 
  [k(f(W))], & \text{if } \dim(W) = \dim(f(W)), \\
  0, & \text{otherwise}.
  \end{cases}
\]

This definition also extends to arbitrary rational equivalence classes of algebraic cycles by linearity. We emphasize that the assumption \( f \) is proper—so that \( f \) takes closed subvarieties to closed subvarieties—was essential to both notions of pushforward associated with the covariant functors \( F \) and \( A_* \). With these prescriptions, MacPherson’s natural transformation then generalizes the Gauss-Bonnet-Chern Theorem to arbitrary varieties. To see this, first note that if \( f: X \to * \) denotes the map from \( X \) to a point, we have

\[
  f_*c_{\text{SM}}(X) = f_*f_*1_X = c_f^*1_X = c_f^*(1_X) = \chi(X)c_f^*(1_X) = \chi(X)[*]
\]

so that \( c_{\text{SM}}(X) \) encodes the Euler characteristic of \( X \) in dimension zero. As such, we denote the pushforward associated with the map \( f \) by \( \int_X : A_*X \to A_** = \mathbb{Z} \) so that we may rewrite the result of the preceding computation as

\[
  \int_X c_{\text{SM}}(X) = \chi(X).
\]

It follows that if \( Y_X \) is a relative variety with associated morphism \( \varphi: Y_X \to X \), the pushforward to a point \( Y \to * \) factors through \( \varphi \); thus, by functoriality and Eq. (3.3), we have

\[
  \int_{Y_X} c_{\text{SM}}(Y_X) = \int_X \varphi_*c_{\text{SM}}(Y_X) = \chi(Y_X),
\]

a fact which will be a key moving forward. In particular, we use the “relative” Gauss-Bonnet-Chern formula

\[
  \int_Y \varphi_*c_{\text{SM}}(Y_X) = \chi(Y_X)
\]
to derive a formula for the Euler characteristic of $Y_X$ in terms of Chow classes on $X$; thus, we need to effectively compute $\varphi_\ast c(Y_X)$ (since we will take $Y_X$ to be smooth). A projecto-relative hypersurface $Y_X$ is embedded in a projective bundle; thus, we have the following diagram:

$$
\begin{array}{ccc}
Y_X & \xrightarrow{i} & \mathbb{P}(\mathcal{E}) \\
\downarrow & & \downarrow \pi \\
X & & 
\end{array}
$$

where $i : Y_X \to \mathbb{P}(\mathcal{E})$ is the inclusion and $\pi : \mathbb{P}(\mathcal{E}) \to X$ is the bundle projection. As such, we have

$$
\varphi_\ast c(Y_X) = \pi_\ast (i_\ast c(Y_X)),
$$

so what we need to effectively compute is $\pi_\ast$, which is the focus of Sec. IV.

### IV. A PUSHFORWARD FORMULA

Let $X$ be a smooth compact variety over $\mathbb{C}$ endowed with a vector bundle $\mathcal{E} \to X$ of rank $r > 0$, and let $\pi : \mathbb{P}(\mathcal{E}) \to X$ denote the projective bundle of lines in $\mathcal{E}$. In this section, we prove a formula for the proper pushforward map $\pi_\ast : A_\ast \mathbb{P}(\mathcal{E}) \to A_\ast X$ associated with the bundle projection $\pi : \mathbb{P}(\mathcal{E}) \to X$. Such a map will enable us to effectively compute $\pi_\ast$ in a way that is independent of the dimension of $X$ and is relative in the sense that it only depends on the rank of $\mathcal{E} \to X$. We denote the dual of a tautological line bundle $\mathcal{O}(-1) \to \mathbb{P}(\mathcal{E})$ by $\mathcal{O}(1) \to \mathbb{P}(\mathcal{E})$, and its associated Chow class in $A_\ast \mathbb{P}(\mathcal{E})$ is denoted by $H$. Crucial to our computations will be the well-known formula of Grothendieck for the Chow group of a projective bundle, namely,

$$
A_\ast \mathbb{P}(\mathcal{E}) \cong A_\ast X[H]/\left( H^2 + c_1(\mathcal{E})H^{-1} + \cdots + c_r(\mathcal{E}) \right)
$$

so that any class in $A_\ast \mathbb{P}(\mathcal{E})$ may be written as a polynomial in $H$ with coefficients in $A_\ast X$ [we note that since $X$ is smooth, the Chow groups $A_\ast \mathbb{P}(\mathcal{E})$ and $A_\ast X$ are in fact rings]. As such, if we let $H^0 = [\mathbb{P}(\mathcal{E})]$, and $\alpha \in A_\ast \mathbb{P}(\mathcal{E})$ is expanded as

$$
\alpha = \alpha_0 H^0 + \alpha_1 H + \alpha_2 H^2 + \cdots,
$$

then by the projection formula, we have

$$
\pi_\ast \alpha = \alpha_0 \pi_\ast H^0 + \alpha_1 \pi_\ast H + \alpha_2 \pi_\ast H^2 + \cdots;
$$

thus, $\pi_\ast$ is determined by how it acts on powers of $H$. As we work over a base $X$ of arbitrary dimension, what our formula then accomplishes is pushing forward all powers of $H$ at once, thus allowing one to compute $\pi_\ast$ in a relative setting.

We recall that the Chern roots of $\mathcal{E}$, denoted $L_1, \ldots, L_n$, are the formal roots of the Chern class of $\mathcal{E}$ so that

$$
c(\mathcal{E}) = (1 + L_1) \cdots (1 + L_n) \in A_\ast X.
$$

We refer to the nonzero Chern roots of $\mathcal{E}$ as the nontrivial Chern roots of $\mathcal{E}$, and since $\mathbb{P}(\mathcal{E})$ is isomorphic to $\mathbb{P}(\mathcal{E} \otimes \mathcal{L})$ for any line bundle $\mathcal{L} \to X$, we may assume without any loss of generality that at least one of the Chern roots of $\mathcal{E}$ is zero. We remark that if $\mathcal{E}$ is in fact the trivial bundle, i.e., if all the Chern roots of $\mathcal{E}$ are zero, then by Ref. 9, Sec. III B, it follows

$$
\pi_\ast H^i = \begin{cases} 1, & \text{if } i = r - 1, \\ 0, & \text{otherwise}. \end{cases}
$$

Thus, we assume from here on that $\mathcal{E}$ is not the trivial bundle of rank $r$ as our formula will be given in terms of the nontrivial Chern roots of $\mathcal{E}$. Alternative notational conventions would allow one to incorporate the case of the trivial bundle into the theorem below (see Remark 4.1); however, we have opted to state this case separately and to assume the bundle $\mathcal{E}$ is nontrivial.

**Theorem 4.1.** Let $L_1, \ldots, L_m$ be the distinct nontrivial Chern roots of $\mathcal{E}$, $k_i \in \mathbb{N}$ be such that the multiplicity of $L_i$ is $k_i + 1$, and let $\alpha \in A_\ast \mathbb{P}(\mathcal{E})$ be given by

$$
\alpha = \alpha_0 + \alpha_1 H + \alpha_2 H^2 + \cdots.
$$
The map $\pi_* : A_*(\mathcal{P}(\mathcal{E})) \to A_*(X)$ is then given by

$$\pi_* \alpha = \left( D \cdot \sum_{i=1}^{m} g_0(x_i) \right) \bigg|_{x_1=-L_1, \ldots, x_n=-L_n} \in A_*(X),$$  \hspace{1cm} (4.3)

where

$$g_0(x_i) = \frac{\alpha(x_i)}{x_i^{\text{rank}(\mathcal{E})} \prod_{i=1, i \neq i}(x_i - x_i)},$$

and $D$ is the linear operator on $A_*(X[x_1, \ldots, x_n])$ given by

$$g \mapsto \frac{1}{k_1! \cdots k_m!} \frac{\partial^{k_1 + \cdots + k_m}}{\partial x_1^{k_1} \cdots \partial x_m^{k_m}} (x_1^{k_1} \cdots x_m^{k_m} \cdot g).$$

Proof. By the projection formula for intersection products, we have

$$\pi_* \alpha = \sum_{j=0} \alpha_j \cdot \pi_*(H^j);$$

thus, $\pi_* \alpha$ is completely determined by the $\pi_*(H^j)$. For this, we use the fact that by Fulton’s definition of Chern class (Ref. 9, Sec. 3.2), we have

$$\pi_* (1 + H + H^2 + \cdots) = \frac{1}{c(\mathcal{E})} = \frac{1}{(1 + L_1)^{k_1} \cdots (1 + L_m)^{k_m}} \in A_*(X),$$

(4.4)

where we recall that the $L_i$ are the distinct nontrivial Chern roots of $\mathcal{E}$. As the proper pushforward of a pure dimensional cycle (not in the kernel of $\pi_*$) preserves its dimension, it follows that $\pi_*(H^j)$ coincides with the term of dimension $\dim(\mathcal{P}(\mathcal{E})) - j$ in the formal series expansion of $(1 + L_1)^{k_1} \cdots (1 + L_m)^{k_m})^{-1}$ [so that $\pi_*(H^j) = 0$ for $j < \text{rank}(\mathcal{E}) - 1$]. Now since

$$\frac{1}{(1 + L_i)^{k_i}} = \frac{1}{k_i!} \frac{d^k}{dx_i^k} \left( \frac{1}{1 - x_i} \right) \bigg|_{x_i=-L_i} = \left( \sum_{j=0} \frac{(k_i + j)!}{k_i! j!} x_i^j \right) \bigg|_{x_i=-L_i},$$

the term of codimension $d$ in $X$ of $c(\mathcal{E})^{-1}$ is precisely

$$\sum_{i_1, \ldots, i_d} \beta^{(k_i)}_{i_1} (L_1)^{i_1} \beta^{(k_2)}_{i_2} (L_2)^{i_2} \cdots \beta^{(k_m)}_{i_m} (L_m)^{i_m},$$

where

$$\beta^{(k_i)}_{i} = \frac{(k_i + i)!}{k_i! i!} = \binom{k_i + i}{k_i}.$$ 

Now let $n = \text{rank}(\mathcal{E}) - 1$. It then follows that $\dim(H^n) = \dim(X)$ so that the term $\pi_*(H^{n+i})$ is of codimension $j$ in $X$. We then have

$$\pi_*(H^{n+i}) = \begin{cases} 0, & \text{for } j < 0, \\ \sum_{i_1, \ldots, i_d} \beta^{(k_i)}_{i_1} (L_1)^{i_1} \beta^{(k_2)}_{i_2} (L_2)^{i_2} \cdots \beta^{(k_m)}_{i_m} (L_m)^{i_m}, & \text{for } j \geq 0. \end{cases}$$

\hspace{1cm} (4.5)

Thus,
\[ \pi_* \mathcal{E} = \pi_* \left( \sum_{j=0} a_{n+1} H^{n+1} \right) \]

\[ = \sum_{j=0} a_{n+1} \cdot \pi_* \left( H^{n+1} \right) \quad \text{(by the projection formula)} \]

\[ \overset{4.5}{=} \sum_{j=0} a_{n+1} \left( \sum_{i_1, \ldots, i_n} \beta_{i_1}^{(k_1)} \left( \cdots \right) \right) \left( \sum_{i_1, \ldots, i_n} \left( \cdots \right) \right) \]

\[ = \sum_{j=0} a_{n+1} \left( \sum_{i_1, \ldots, i_n} \frac{1}{k_1! \cdots k_m!} \frac{\partial \cdots \partial \partial}{\partial x_1 \cdots \partial x_m} \left( \sum_{i_1, \ldots, i_n} \left( \cdots \right) \right) \right) \]

\[ = \sum_{j=0} a_{n+1} \left( \sum_{i_1, \ldots, i_n} \frac{1}{k_1! \cdots k_m!} \frac{\partial \cdots \partial \partial}{\partial x_1 \cdots \partial x_m} \left( \sum_{i_1, \ldots, i_n} \left( \cdots \right) \right) \right) \]

\[ \overset{4.6}{=} \sum_{j=0} a_{n+1} \left( D \sum_{i=1}^m x_i^{m_{i+1}+1} \right) \]

\[ = \left( D \sum_{i=1}^m \frac{a - \alpha_1 x_1 + \cdots + \alpha_{\text{rank}(\mathcal{E})} x_i^{\text{rank}(\mathcal{E})-2}}{x_i^{\text{rank}(\mathcal{E})-m} \prod_{j=1, j \neq i}^m (x_i - x_j)} \right) \]

The conclusion follows from the last expression; note that in the seventh equality, we used the following fact (see Ref. 5, Theorem 3.2)

\[ \sum_{i_1, \ldots, i_n} x_1^{i_1} x_2^{i_2} \cdots x_m^{i_m} = \sum_{i=1}^m x_i^{m_{i+1}+1} \]

Clearly formula (4.3) is symmetric in the distinct Chern roots of \( \mathcal{E} \) so that the end result may be expressed in terms of the Chern classes \( c_i(\mathcal{E}) \) and the \( a_i \) for \( j \geq n \). As we view the operation \( \pi_* \) as a relative form of integration, it is interesting to note that the appearance of the differential operator on the right-hand side of formula (4.3) gives it the flavor of a “Stokes-type formula.” It follows from formula (4.6) (along with degree considerations) that terms of the form \( L_{\text{rank}(\mathcal{E})-m} \prod_{j=1, j \neq i}^m (L_i - L_j) \) appearing in final expression for \( \pi_* \mathcal{E} \) in fact cancel once put over a common denominator. As such, in practice one may in fact avoid the use of the differential operator \( D \) by first assuming all the nontrivial Chern roots are distinct and then evaluating the final simplified rational expression at the possibly nondistinct total number of nontrivial Chern roots of \( \mathcal{E} \).

**Remark 4.1.** Similar to the discussion above, if one changes the notational convention so that the last (or first) Chern root is assumed to be zero and makes no assumptions on the remainder of the roots, then the \( L_i \)’s in Theorem 4.1 can be treated as formal symbols and zero values can be substituted in after clearing denominators in the pushforward resulting from the formula in Theorem 4.1. In particular, suppose we have a vector bundle \( \mathcal{E} \rightarrow X \) of rank \( r \) with Chern roots \( a_1, \ldots, a_r \). If, as above, we choose \( a_r \) and set \( \mathcal{L} \rightarrow X \) to be a line bundle whose first Chern class is \(-a_r\), then after tensoring \( \mathcal{E} \) with \( \mathcal{L} \) we get a vector bundle [which can still be called \( \mathcal{E} \) as this yields an isomorphic projectivization \( \mathbb{P}(\mathcal{E}) \)] with Chern roots \( L_1, \ldots, L_{r-1} \) and \( L_r = 0 \). We could then define \( L_1, \ldots, L_{r-1} \) as nontrivial Chern roots (regardless of their values and allowing them to be zero). With this convention, we would apply the formula of Theorem 4.1 treating the Chern roots \( L_1, \ldots, L_{r-1} \) as formal symbols and evaluating them after clearing denominators. In this way, one could avoid assuming that the Chern roots in Theorem 4.1 are nonzero. However, since only the nonzero Chern roots determine the pushforward (for nontrivial bundles), we have opted for the notational convention which assumes that \( L_i \)’s in Theorem 4.1 are nonzero.

For projective bundles of small rank, formula (4.3) is reasonable to apply by hand although in any case, a computer implementation is straightforward and is of negligible cost. We note that such an implementation may be of utility for software packages computing characteristic classes of varieties. In particular, an implementation of (4.3) allows the applicability setting of algorithms for computing singular Chern classes and Euler characteristics of (possibly singular) projective varieties and schemes (such as Refs. 12 and 11) to be broadened to the setting of projective bundles. To this end, and to simplify computations for the interested reader, we provide a test implementation in the form of a Macaulay2 package which can be downloaded from [https://github.com/Martin-Helmer/PBF](https://github.com/Martin-Helmer/PBF).
We note that when \( \mathcal{E} \) is the direct sum of tensor powers of a fixed line bundle on \( X \), we recover the main formula derived in Ref. 8, Theorem 1.1, and when \( \mathcal{E} \) is the direct sum of three distinct line bundles, we recover a formula appearing in Ref. 7, Sec. 2.7.

V. RELATIVE CHERN CLASS

We recall that in Sec. III, we saw that if \( \varphi: Y_X \rightarrow X \) is a relative variety, then

\[
\chi(Y_X) = \int_X \varphi_* c(Y_X)
\]

so that explicitly computing the RHS of Eq. (5.1) yields a "Sethi-Vafa-Witten formula" for the Euler characteristic of \( Y_X \) in terms of a Chow class on \( X \). In this section, we discuss the precise sense in which \( \varphi_* c(Y_X) \) is the Chern class of the morphism \( \varphi: Y_X \rightarrow X \) and then use the functorial formalism of Sec. III to derive a formula for \( \varphi_* c(Y_X) \) when \( Y_X \) is the projecto-relative hypersurface \( Z_X(n, d) \) defined in Sec. II. An explicit formula for \( Y_X \), an arbitrary projecto-relative hypersurface, is then derived in Sec. VI.

Let \( V \) be a variety and denote by \( K_0(\text{Var}_V) \) the free \( \mathbb{Z} \)-module generated by isomorphism classes of proper morphisms to \( V \), modulo the relation

\[
[Y \xrightarrow{\psi} V] = [Z \xrightarrow{\psi \mid_Z} V] + [U \xrightarrow{\psi \mid_U} V],
\]

whenever \( Z \) is a closed subvariety of \( Y \) with open complement \( U \). We may endow \( K_0(\text{Var}_V) \) with a ring structure by setting

\[
[Y \xrightarrow{\psi} V] [W \xrightarrow{\vartheta} V] = [Y \times_V W \rightarrow V],
\]

where \( Y \times_V W \rightarrow V \) denotes the fibered product of \( Y \) with \( W \) over \( V \) (with respect to the morphisms \( \psi \) and \( \vartheta \)). We refer to the ring \( K_0(\text{Var}_V) \) as the relative Grothendieck ring of varieties (over \( V \)). When \( V = \ast \) is a point, the relative Grothendieck ring is often denoted \( K_0(\text{Var}_\ast) \) and referred to simply as the Grothendieck ring of varieties. Now given a proper morphism \( V \xrightarrow{\varphi} S \), we define an associated homomorphism

\[
K_0(f): K_0(\text{Var}_V) \rightarrow K_0(\text{Var}_S),
\]

given by

\[
[Y \xrightarrow{\psi} V] \mapsto [Y \xrightarrow{\varphi \circ \psi} S].
\]

With such prescriptions, \( K_0(\text{Var}_\ast) \) is then a covariant functor from varieties to groups with respect to proper morphisms, which we refer to as the relative Grothendieck functor. Moreover, there exists a natural transformation of functors

\[
n: K_0(\text{Var}_\ast) \rightarrow F,
\]

given by

\[
n([Y \xrightarrow{\psi} V]) = \psi_* 1_Y \in F(V),
\]

where we recall that \( \psi_* 1_Y \) is the pushforward to \( V \) of the constructible function \( 1_Y \) [as prescribed by Eq. (3.2)]. Then, composing \( n: K_0(\text{Var}_\ast) \rightarrow F \) with the MacPherson natural transformation \( c_*: F \rightarrow A_* \) yields

\[
c_*(\psi_* 1_Y) = \psi_* (c_*(1_Y)) = \psi_* c_{\text{SM}}(Y) \in A_* V.
\]

As such, after denoting the composition \( c_* \circ n \) simply by \( c \), we have

\[
c([Y \xrightarrow{\psi} V]) = \psi_* c_{\text{SM}}(Y),
\]

which we refer to as the relative Chern class of the morphism \( \psi: Y \rightarrow V \) (though we should really say relative Chern class of the class of the morphism \( \psi: Y \rightarrow V \) in the relative Grothendieck ring), which we will often denote by \( c(\psi) \). In such a framework, the Chern-Schwartz-MacPherson class of a variety \( V \) is the relative Chern class of the identity morphism \( 1_V: V \rightarrow V \), i.e.,

\[
c_{\text{SM}}(V) = c(1_V) \in A_* V
\]

(for more on relative characteristic classes, see Refs. 3 and 4).

Now, let \( X \) be a smooth compact base variety and let \( \varphi: Z_X(n, d) \rightarrow X \) be the projecto-relative hypersurface defined in Sec. II, namely, the projecto-relative hypersurface given by

\[
Z_X(n, d) : (x_1^d + \cdots + x_n^d + fx_1x_0^{d-1} + gx_0^d = 0) \subset \mathbb{P}(\delta),
\]
where $\mathcal{E} \to X$ is the direct sum of the trivial line bundle $\mathcal{O} \to X$ with $n$-copies of an ample line bundle $\mathcal{L} \to X$. For ease of notation, we denote $Z_X(n, d)$ simply by $Z_X$ from here on. By Eq. (5.2), we have
\[
c(\varphi) = c_*(\varphi_* 1_{Z_X}).
\]
We now focus on the computation of $\varphi_* 1_{Z_X}$. Recall that the discriminant of $Z_X$ is given by
\[
\Delta_d : \{ (d-1)^d f + d(-d)^d g = 0 \} \subset X,
\]
and for $Z_X$ to be smooth, we make the assumption that the hypersurfaces
\[
F : (f = 0) \subset X \quad \text{and} \quad G : (g = 0) \subset X
\]
are smooth and intersect transversally. This further implies that the codimension 2 complete intersection
\[
C : (f = g = 0) \subset X
\]
is smooth as well. We can then stratify $X$ according to the fibers of $\varphi : Z_X \to X$. The fibers of $\varphi$ over $X \setminus \Delta_d$ are smooth degree $d$ hypersurfaces whose homeomorphism class is denoted by $F_0$, the fibers over $\Delta_d \setminus C$ are singular fibers whose homeomorphism class is denoted by $F_1$, and the fibers over $C$ are singular fibers whose homeomorphism class is denoted by $F_2$. By the definition of pushforward of constructible functions given by Eq. (3.2), we have
\[
\varphi_* 1_{Z_X} = \chi(F_0)(1_X - 1_{\Delta_d}) + \chi(F_1)(1_{\Delta_d} - 1_C) + \chi(F_2) 1_C
\]
so that
\[
c(\varphi) = c_* \circ \varphi_*(1_{Z_X})
\]
\[
= c_*(\chi(F_0) 1_X + (\chi(F_1) - \chi(F_0)) 1_{\Delta_d} + (\chi(F_2) - \chi(F_1)) 1_C)
\]
\[
= \chi(F_0) c_{\text{SM}}(X) + (\chi(F_1) - \chi(F_0)) c_{\text{SM}}(\Delta_d) + (\chi(F_2) - \chi(F_1)) c_{\text{SM}}(C).
\]
Now since $X$ and $C$ are smooth, their CSM-classes coincide with their usual Chern classes $c(X)$ and $c(C)$, which are given by
\[
c(X) = c(TX) \cap [X] \quad \text{and} \quad c(C) = c(TX) \cap \left( \frac{[F] \cdot [G]}{(1 + [F])(1 + [G])} \right).
\]
The details of the computation of $c_{\text{SM}}(\Delta_d)$ would take us too far afield (i.e., to the theory of Segre classes of singular schemes of hypersurfaces), but $c_{\text{SM}}(\Delta_d)$ was computed in Ref. 1, Sec. 4.2 for the case $d = 3$, and the computation for general $d$ is no different. As such, we have
\[
c_{\text{SM}}(\Delta_d) = c(TX) \cap \left( \frac{\Delta_d}{1 + [\Delta_d]} + \frac{(d-2)(d-1)[F] \cdot [G]}{(1 + [\Delta_d])(1 + [F]) + (1 - d)[F] + 2 - d}[G]) \right)
\]
thus, we have an explicit formula for $c(\varphi)$ once we know the Euler characteristics of $F_0$, $F_1$, and $F_2$. The Euler characteristic of a smooth hypersurface of degree $d$ in $\mathbb{P}^n$ is a polynomial in $d$, namely,
\[
\epsilon_s(d) = -\sum_{k=0}^{n-1} \binom{n+1}{k} (-d)^{n-k}
\]
so that $\chi(F_0) = \epsilon_s(d)$. The singular fibers $F_1$ and $F_2$ both have an isolated singular point whose Milnor numbers are given by $(-1)^n(d-1)^{n-1}$ and $(-1)^n(d-1)^n$, respectively; thus, their Euler characteristics are given by
\[
\chi(F_1) = \epsilon_s(d) + (-1)^n(d-1)^{n-1}, \quad \chi(F_2) = \epsilon_s(d) + (-1)^n(d-1)^n.
\]
We then have
\[
c(\varphi) = \epsilon_s(d) \cdot c(X) + (-1)^n(d-1)^{n-1} \cdot c_{\text{SM}}(\Delta_d) + (-1)^n((d-1)^n - (d-1)^{n-1}) \cdot c(C),
\]
which after a lot of messy algebra yields
Then, \( \alpha \) then takes the form—which will be seen to arise from the application of Theorem 4.1 to the current setting in proof of Theorem 6.1 below—is then given canceling common factors from the numerator and denominator of the form

\[ \text{(5.6)} \]

where we recall \( n \) and in (i) of the proof of Theorem 3.2 of Ref. 5, it is shown that for 0 \( \leq d \leq m \), we have

\[ \text{(6.4)} \]

Proof. The left-hand side of Eq. (6.4) may be expanded as

\[ \sum_{i=1}^{m} \alpha_i x_i \frac{x_i}{\prod_{j=1}^{m} (x_j - x_i)} + \sum_{i=1}^{m} \frac{1}{\prod_{j=1}^{m} (x_j - x_i)} + \cdots + \sum_{i=1}^{m} \frac{x_i}{\prod_{j=1}^{m} (x_j - x_i)}, \]

and in (i) of the proof of Theorem 3.2 of Ref. 5, it is shown that for 0 \( \leq p \leq m - 2 \), we have
\[ \sum_{i=1}^{m} \frac{x_i^p}{\prod_{i=1}^{m} (x_i - x_i^p)} = 0, \]  
(6.5)

from which the lemma follows. We note that there is in fact a typo in formula (i) of Theorem 3.2 of Ref. 5; however, we have corrected the typo in formula (6.5) above. In particular, in Ref. 5, they have incorrectly switched the bounds between the range values denoted \( p \) and \( m \). In our notation.

\[ \square \]

**Proof of Theorem 6.1.** It suffices to prove the case where the nontrivial Chern roots of \( \beta \) are all distinct since one may set them equal to each other after the final result if some of them appear with multiplicity. In such a case, we have \( m = n \). Now let \( \mathcal{O}(Y_X) \to \mathbb{P}(\beta) \) denote the line bundle corresponding to the divisor class of \( Y_X \) [whose restriction to \( Y_X \) yields the normal bundle to \( Y_X \) in \( \mathbb{P}(\beta) \)]. In order to write an explicit expression for \( c(\phi) \), we first write an expression for \( c(i) \), where \( i : Y 
\to \mathbb{P}(\beta) \) denotes the natural inclusion. For this, we consider the following exact sequences of vector bundles (as Chern classes are multiplicative)\

\[ 0 \to TY_X \to i^* TP(\beta) \to i^* \mathcal{O}(Y_X) \to 0, \]

\[ 0 \to T_{\mathbb{P}(\beta)/X} \to TP(\beta) \to \pi^* TX \to 0, \]

\[ 0 \to \mathcal{O} \to \pi^*(\beta) \oplus \mathcal{O}(1) \to T_{\mathbb{P}(\beta)/X} \to 0, \]

The first sequence (from the top) is standard, the second one may take as the definition of the relative tangent bundle \( T_{\mathbb{P}(\beta)/X} \), and the third is given in B.5.8 of Ref. 9. We then have

\[ c(i) = i_* (c(TY_X) \cap [Y_X]) \]

\[ = i_* \left( \frac{c(i^* TP(\beta)) \cap [Y_X]}{c(i^* \mathcal{O}(Y_X))} \right) \]

\[ = \frac{c(\pi^*(\beta) \oplus \mathcal{O}(1)) \cdot c(\pi^* TX)}{c(\mathcal{O}(Y_X))} \cap i_* [Y_X] \]

\[ = \frac{c(\pi^*(\beta) \oplus \mathcal{O}(1)) \cdot c(\pi^* TX)}{c(\mathcal{O}(Y_X))} \cap \left( c(\mathcal{O}(Y_X)) \cap \pi^*[X] \right) \]

\[ = \frac{c(\pi^*(\beta) \oplus \mathcal{O}(1)) \cdot c(\mathcal{O}(Y_X))}{c(\mathcal{O}(Y_X))} \cap \left( c(\pi^* TX) \cap \pi^*[X] \right) \]

\[ = \frac{c(\pi^*(\beta) \oplus \mathcal{O}(1)) \cdot c(\mathcal{O}(Y_X))}{c(\mathcal{O}(Y_X))} \cap \pi^* c(id_X), \]

where the third equality follows from the projection formula, the fourth from the fact that \( \pi^*[X] = [\mathbb{P}(\beta)] \) [since \( i_* [Y_X] = c_1(\mathcal{O}(Y_X)) \cap [\mathbb{P}(\beta)] \)], the fifth from the commutativity of Chern classes, and the sixth by the behavior of Chern classes with respect to pullback.

Now since \((0, L_1, \ldots, L_m)\) are the Chern roots of \( \beta \) (which we recall we have assumed to be distinct), we have that the Chern roots of \( \pi^*(\beta) \oplus \mathcal{O}(1) \) are then \((H, L_1 + H, \ldots, L_m + H)\) (note that technically, the Chern roots of this form \( \pi^* L_i + H \), but we have omitted the pullbacks). Thus,

\[ c(i) = \frac{(1 + H)(1 + H + L_1) \cdots (1 + H + L_m) \cdot [Y_X]}{1 + [Y_X]} \cdot \pi^* c(id_X) \]

so that

\[ c(\phi) = \varphi_* c(id_{Y_X}) \]

\[ = \pi_* \circ i_* c(id_{Y_X}) \]

\[ = \pi_* c(i) \]

\[ = \pi_* \left( \frac{(1 + H)(1 + H + L_1) \cdots (1 + H + L_m) \cdot [Y_X]}{1 + [Y_X]} \cdot \pi^* c(id_X) \right) \]

\[ = \pi_* \left( \frac{(1 + H)(1 + H + L_1) \cdots (1 + H + L_m) \cdot [Y_X]}{1 + [Y_X]} \right) \cdot c(id_X), \]

where the second equality follows from functoriality and the fifth follows via the projection formula. The theorem then follows once we show
\[ \pi_* \left( \frac{(1 + H)(1 + H + L_1) \cdots (1 + H + L_m)}{1 + [Y_X]} \right) = Q_d(\varepsilon, \beta), \]

where we recall that the class of \( Y_X \) is of the form \([Y_X] = dH + \pi^* \beta\) for some divisor \( \beta \) in \( X \). So now let \( \alpha(H) \) be given by

\[ \alpha(H) = \frac{(1 + H) \cdot \prod_{i=1}^{m}(1 + H + L_i) \cdot [Y_X]}{1 + [Y_X]} \]

Applying Theorem 4.1 along with Lemma 6.2 to the class \( \alpha(H) \) then yields

\[ \pi_* \alpha(H) = \sum_{\alpha_0} \frac{\alpha(x_i) - \alpha_0}{\prod_{j=1}^{n}(x_j - x_i)} \frac{\prod_{\alpha_j \neq \alpha_0}(1 + L_j)}{\prod_{j=1}^{n}(1 + L_j)} \beta \cdot dL_j = \frac{\prod_{\alpha_j \neq \alpha_0}(1 + L_j)}{\prod_{j=1}^{n}(1 + L_j)} \beta \cdot dL_j \]

which coincides with \( Q_d(\varepsilon, \beta) \) by definition, thus concluding the proof.

We note that for concrete realizations of \( Y_X \), the associated pushforward formula and the form of \( Q_d(\varepsilon, \beta) \) will often be quite simple. In particular, consider the case \( Y_X = Z_X(n, d) \) as defined in Sec. II and let \( Q_{n,d}(L) = Q_d(\varepsilon, \beta) \) be the resulting expression in \( L, n, \) and \( d \). First compute \( Q_d(\varepsilon, \beta) \) for \( Y_X = Z_X(2, d) \) using Theorem 4.1. We treat the repeated Chern root \( L \) as two distinct Chern roots \( L_1, L_2 \). We now apply Eq. (6.1) with the two distinct Chern roots. The summation in the first term is

\[ \frac{(L_1 - 1)(L_1 - L_2 - 1)(dL_1 - \beta) (\beta + 1) + \beta(L_2 + 1)(L_1 + 1)(dL_1 - (\beta + 1))}{L_1(L_1 - L_2)(\beta + 1)(dL_1 - (\beta + 1))} \]

and the second term in the summation is

\[ \frac{(L_2 - 1)(L_1 - L_2 + 1)(dL_2 - \beta) (\beta + 1) - \beta(L_2 + 1)(L_1 + 1)(dL_2 - (\beta + 1))}{L_2(L_1 - L_2)(\beta + 1)(dL_2 - (\beta + 1))} \]

Adding these two terms, we see that each term in the resulting numerator has a factor of \([L_1L_2(L_1 - L_2)]\); this term also appears in the denominator. Canceling these from the numerator and denominator, we obtain \( Q_d(\varepsilon, \beta) = \frac{P(L_1, L_2, d, \beta)}{(\cdots)(1 + (1 + p) \cdots)(1 + \cdots)(\cdots)} \), where the numerator \( P(L_1, L_2, d, \beta) \) is

\[ 3L_1L_2d^2 \beta^2 + 2L_1L_2d^2 - 3L_1d^2 \beta^2 - 3L_2d^2 \beta^2 - L_1d^2 - L_2d^2 - 4L_1d \beta - 4L_2d \beta + 3 \beta^2 - L_1d - L_2d - d^2 + 3d \beta + 6 \beta^2 + 3d + 3 \beta. \]

Substituting in \( L_1 = L_2 = L \) and \( \beta = dL \), we obtain

\[ Q_{n,d}(L) = \frac{Ld^2 + Ld - d^2 + 3d}{dL + 1} = \frac{dL + d(3 - d)}{dL + 1}. \]

Now consider the case \( Y_X = Z_X(3, d) \); applying (6.1) with the three distinct Chern roots \( L_1, L_1, L_3 \), simplifying with a computer algebra system, and substituting in \( L_1 = L_2 = L = L \) and \( \beta = dL \), we obtain

\[ Q_{n,d}(L) = \frac{Ld^3 + 3Ld^2 + d^3 + Ld - 4d^2 + 6d}{dL + 1} = \frac{dL(-d^2 + 3d + 1) + d(d^2 - 4d + 6)}{dL + 1}. \]

By induction, we see that

\[ Q_{n,d}(L) = \frac{dL \left( 1 + \sum_{i=1}^{n-1}(-1)^{i+1} \binom{n}{i+1}d^i \right) + d \left( \sum_{i=0}^{n-1}(-1)^i \binom{n+1}{i+2}d^i \right)}{1 + dL}. \]

In particular, for the case \( Y_X = Z_X(n, d) \) as defined in Sec. II, we have

\[ Q_d(\varepsilon, \beta) = \frac{c_n(d) + (c_{n-1}(d) + 1) dL}{1 + dL}. \]

This reconfirms the derivation of (5.6) using singularity theoretic methods. We remark that using the methods of Sec. V to compute \( c(\varphi) \) will quickly become impractical as one considers more complicated examples since the singularities of its fibers and complexity of its
discriminant will worsen significantly. In fact, in many such examples, just computing the discriminant itself can be unfeasible, let alone its CSM class. On the other hand, computing \( c(\varphi) \) via the pushforward formula remains the same as it reduces the computation of \( c(\varphi) \) to simple algebraic manipulations which are irrespective of the singularities of the fibers and discriminant of \( \varphi: Y_X \rightarrow X \).

Now let \( Q_i \) be the polynomial in \( t \) which comes from evaluating \( Q_\alpha(\delta, \beta) \) at \( H = tH, \beta = t\beta \), and \( L_i = tL_i \) for \( i = 1, \ldots, n \), and denote by \( c_i(X) \) the Chern polynomial of \( X \) so that

\[
c_i(X) = 1 + c_1(X)t + c_2(X)t^2 + \cdots + c_{\dim(X)}(X)t^{\dim(X)},
\]

and denote the map which takes a polynomial in \( t \) to its \( k \)th coefficient by \([t^k]\). An immediate corollary of Theorem 6.1 is then given by the following:

**Corollary 6.3.** The Euler characteristic of \( Y_X \) is given by the Sethi-Vafa-Witten formula

\[
\chi(Y_X) = \int_X [t^{\dim(X)}](Q_i \cdot c_i(X)).
\]

**Proof.** Rewriting the relative Gauss-Bonnet formula (3.4) using the notations of Sec. V yields

\[
\chi(Y_X) = \int_X c(\varphi),
\]

and since

\[
c(\varphi) = \sum_{k=0}^{\dim(X)} [t^k](Q_i \cdot c_i(X)),
\]

the result follows from the definition of the map \( \int_X : A_X \rightarrow \mathbb{Z} \). \[\square\]

We now apply Corollary 6.3 to \( Y_X = Z_X(n, d) \) as defined in Sec. II. Setting \( m = \dim(X) \), we have

\[
\chi(Z_X(n, d)) = e_n(d)c_m(X) + (-dL)^m(e_n(d) - e_{n-1}(d) - 1) + \sum_{i=1}^{m-1} (-dL)^i(e_n(d) - e_{n-i}(d) - 1)c_{m-i}(X). \tag{6.7}
\]

For a second concrete illustration, we apply Corollary 6.3 to the elliptic fibration introduced in Sec. I.

**Example 6.4.** The Weierstrass equation

\[
y^2z = x^3 + fxz^2 + gz^3
\]

defines a projecto-relative hypersurface \( \varphi: Y_X \rightarrow X \) by taking \( x \) as a section of \( \mathcal{O}(1) \otimes \pi^* \mathcal{L}^2 \), \( y \) as a section of \( \mathcal{O}(1) \otimes \pi^* \mathcal{L}^3 \), \( z \) as a section of \( \mathcal{O}(1), \) \( f \) as a section of \( \pi^* \mathcal{L}^4 \), and \( g \) as a section of \( \pi^* \mathcal{L}^6 \) (with \( \mathcal{L} \rightarrow X \) an ample line bundle). In such a case, we have

\[
\delta = \mathcal{O} \otimes \mathcal{L}^2 \otimes \mathcal{L}^3,
\]

and \( [Y_X] = 3H + 6L \) (where \( L \) is the Chern root of \( \mathcal{L} \rightarrow X \)) so that \( \beta \) in this case is \( 6L \). The rational expression \( Q_\delta(\delta, 6L) \) is then given by

\[
Q_\delta(\delta, 6L) = \frac{L - 1}{L} + \frac{(1 + 2L)(1 + 3L)(6L)}{6L^2(1 + 6L)} = \frac{12L}{1 + 6L}.
\]

Applying Corollary 6.3 and taking \( \mathcal{L}^{-1} = -K_X \) (so that \( X \) must be Fano) then recover the Sethi-Vafa-Witten formula

\[
\chi(Y_X) = \int_X 12c_1(X) \sum_{i=0}^{\dim(X) - 1} c_i(X)(-6c_1(X))^{\dim(X) - 1 - i}, \tag{6.8}
\]

which was first proved in Ref. 1 by the singularity-theoretic methods used in Sec. V. For general \( \mathcal{L} \), we have the Sethi-Vafa-Witten formula
\[ \chi(Y_X) = \int_X 12L \sum_{i=0}^{\dim(X)-1} c_i(X)(-6L)^{\dim(X)-1-i}. \]  

(6.9)

Moreover, since

\[ c(\varphi) = \sum_{i=0}^{\dim(X)} \left[ i^j \left( \frac{12L}{1 + 6Lt} \cdot c_i(X) \right) \right], \]

we have

\[ c(\varphi) = \sum_{j=1}^{\dim(X)} \left( 12L \sum_{i=0}^{j-1} c_i(X)(-6L)^{j-1-i} \right) \]

(6.10)

so that the entire relative Chern class may be obtained by truncating the Sethi-Vafa-Witten formula (6.9). In particular, in the case \( L = c_1(X) \), (6.10) yields formula (1.4) from Sec. 1.

ACKNOWLEDGMENTS

Martin Helmer was supported by an NSERC (Natural Sciences and Engineering Research Council of Canada) postdoctoral fellowship during the preparation of this work. We are grateful to the Institute of Mathematical Research at the University of Hong Kong for hosting Martin Helmer’s visit there, where part of this work was completed.
