MODEL CATEGORIES OF QUIVER REPRESENTATIONS

HENRIK HOLM AND PETER JØRGENSEN

Abstract. Gillespie’s Theorem gives a systematic way to construct model category structures on $C(M)$, the category of chain complexes over an abelian category $M$.

We can view $C(M)$ as the category of representations of the quiver $\cdots \to 2 \to 1 \to 0 \to -1 \to -2 \to \cdots$ with the relations that two consecutive arrows compose to $0$. This is a self-injective quiver with relations, and we generalise Gillespie’s Theorem to other such quivers with relations. There is a large family of these, and following Iyama and Minamoto, their representations can be viewed as generalised chain complexes.

Our result gives a systematic way to construct model category structures on many categories. This includes the category of $N$-periodic chain complexes, the category of $N$-complexes where $\partial^N = 0$, and the category of representations of the repetitive quiver $\mathbb{Z}A_n$ with mesh relations.

0. Introduction

Gillespie’s Theorem permits the construction of model category structures on categories of chain complexes. We will generalise it to representations of self-injective quivers with relations, which can be viewed as generalised chain complexes by the work of Iyama and Minamoto, see [17] and [18, sec. 2].

0.i. Outline.

Let $\mathcal{M}$ be an abelian category. An abelian model category structure on $C(\mathcal{M})$, the category of chain complexes over $\mathcal{M}$, consists of three classes of morphisms, (fib, cof, weq), known as fibrations, cofibrations, and weak equivalences, subject to several axioms, see [15, def. 2.1] and [26, sec. I.1]. It provides an extensive framework for the construction and manipulation of the localisation $\text{weq}^{-1}C(\mathcal{M})$, where the morphisms in weq have been inverted formally. Some of the localisations thus obtained are of considerable interest, not least the derived category $D(\mathcal{M})$.

Hovey’s Theorem says that each abelian model category structure can be constructed from two so-called complete, compatible cotorsion pairs, see Theorem [1.2]. This motivates Gillespie’s Theorem, which takes a hereditary cotorsion pair in $\mathcal{M}$ and produces two compatible cotorsion pairs in $C(\mathcal{M})$, see Theorem [0.3].

Gillespie’s Theorem can be viewed as a result on quiver representations since $C(\mathcal{M})$ is the category of representations of $Q$ with values in $\mathcal{M}$, where $Q$ is the following self-injective quiver with relations.

\[
\begin{align*}
\text{Quiver:} & \quad \cdots \to 2 \to 1 \to 0 \to -1 \to -2 \to \cdots \\
\text{Relations:} & \quad \text{Two consecutive arrows compose to } 0.
\end{align*}
\]

(0.1)

The notion of self-injectivity is made precise in Paragraph [2.4]. This paper will generalise Gillespie’s Theorem to other self-injective quivers with relations. They form a large family, see for example Equations (0.3) and (0.4) and Section [0.viii].
Let \( k \) be a field, \( R \) a \( k \)-algebra, \( Q \) a self-injective quiver with relations over \( k \), and let \( \mathcal{X} \) be the category of representations of \( Q \) with values in \( _R\text{Mod} \), the category of \( R \)-left-modules. Our main theorem, Theorem \( \text{(A)} \), takes a hereditary cotorsion pair in \( _R\text{Mod} \) and produces two compatible cotorsion pairs in \( \mathcal{X} \). It specialises to Gillespie’s Theorem for \( \mathcal{M} = _R\text{Mod} \) if \( Q \) is the quiver with relations from (0.1).

0.ii. Cotorsion pairs.

Let \( \mathcal{Y} \) be an abelian category. If \( \Gamma \) and \( \Delta \) are classes of objects of \( \mathcal{Y} \), then we write
\[
\Gamma^\perp = \{ Y \in \mathcal{Y} \mid \text{Ext}_{\mathcal{Y}}(C,Y) = 0 \text{ for } C \in \Gamma \} \quad \text{and} \quad \perp \Delta = \{ Y \in \mathcal{Y} \mid \text{Ext}_{\mathcal{Y}}(Y,D) = 0 \text{ for } D \in \Delta \}.
\]

**Definition 0.1.** Recall the following from the literature.

1. A cotorsion pair in \( \mathcal{Y} \) is a pair \( (\Gamma, \Delta) \) of classes of objects of \( \mathcal{Y} \) such that \( \Gamma = \perp \Delta \) and \( \Gamma^\perp = \Delta \), see [28, p. 12]. A cotorsion pair \( (\Gamma, \Delta) \) is determined by each of the classes \( \Gamma \) and \( \Delta \), because it is equal to \( (\Gamma, \Gamma^\perp) \) and to \( (\perp \Delta, \Delta) \).

2. The cotorsion pair \( (\Gamma, \Delta) \) in \( \mathcal{Y} \) is complete if each \( Y \in \mathcal{Y} \) permits short exact sequences \( 0 \to D \to C \to Y \to 0 \) and \( 0 \to Y \to D' \to C' \to 0 \) with \( C, C' \in \Gamma \) and \( D, D' \in \Delta \), see [12, lem. 5.20].

3. The cotorsion pair \( (\Gamma, \Delta) \) is hereditary if \( \Gamma \) is closed under kernels of epimorphisms and \( \Delta \) is closed under cokernels of monomorphisms, see [12, lem. 5.24].

4. The cotorsion pairs \( (\Phi, \Phi^\perp) \) and \( (\perp \Psi, \Psi) \) in \( \mathcal{Y} \) are compatible if they satisfy the following conditions, see [10, sec. 1].

\[
\begin{align*}
(\text{Comp1}) \quad & \text{Ext}_{\mathcal{Y}}^1(\Phi, \Psi) = 0. \\
(\text{Comp2}) \quad & \Phi \cap \Phi^\perp = \perp \Psi \cap \Psi.
\end{align*}
\]

Condition (Comp1) is equivalent to \( \Phi \subseteq \perp \Psi \) and to \( \Phi^\perp \supseteq \Psi \). It is not symmetric in the two cotorsion pairs; their order matters.

Note that our definition of compatibility is weaker than Gillespie’s from [11, def. 3.7], and that his cotorsion pairs \( (\mathcal{A}, \text{dg} \mathcal{B}) \) and \( (\text{dg} \mathcal{A}, \mathcal{B}) \) in \( \mathcal{C}(\mathcal{M}) \) from [11, prop. 3.6] are always compatible in our sense. Indeed, \( \mathcal{A} \cap \text{dg} \mathcal{B} \) and \( \text{dg} \mathcal{A} \cap \mathcal{B} \) are both equal to the class of split exact complexes with terms in \( \mathcal{A} \cap \mathcal{B} \).

5. Let \( (\Gamma, \Delta) \) be a cotorsion pair in \( \mathcal{Y} \), and let \( \mathcal{C} \) be a class of objects in \( \mathcal{Y} \). If \( \Delta = \mathcal{C}^\perp \), then we say that \( (\Gamma, \Delta) \) is generated by \( \mathcal{C} \). If \( \Gamma = \perp \mathcal{C} \), then we say that \( (\Gamma, \Delta) \) is cogenerated by \( \mathcal{C} \). See [12, def. 5.15].

For example, if \( \mathcal{Y} \) has enough projective objects, then (projective objects, \( \mathcal{Y} \)) is called the projective cotorsion pair. If \( \mathcal{Y} \) has enough injective objects, then (\( \mathcal{Y} \), injective objects) is called the injective cotorsion pair. These cotorsion pairs are complete and hereditary. Note that the triangulated version of compatible cotorsion pairs was investigated by Nakaoka under the name concentric twin cotorsion pair, see [24, def. 3.3].

0.iii. Hovey’s Theorem: Abelian model category structures.

We will not reproduce Hovey’s Theorem in full, but rather state the following result, which motivates the interest in compatible cotorsion pairs and dovetails with Gillespie’s Theorem.

**Theorem 0.2** ([9, prop. 2.3 and sec. 4.2], [10, thm. 1.1], [15, thm. 2.2]). Let \( (\Phi, \Phi^\perp) \) and \( (\perp \Psi, \Psi) \) be complete, hereditary, compatible cotorsion pairs in the abelian category \( \mathcal{Y} \).
There is a class $\mathcal{W}$ of objects, often referred to as trivial, characterised by

$$\mathcal{W} = \{ Y \in \mathcal{Y} \mid \text{there is a short exact sequence } 0 \to P \to F \to Y \to 0 \text{ with } P \in \Psi, F \in \Phi \}$$

$$= \{ Y \in \mathcal{Y} \mid \text{there is a short exact sequence } 0 \to Y \to P' \to F' \to 0 \text{ with } P' \in \Psi, F' \in \Phi \}.$$ 

Moreover, there is a model category structure on $\mathcal{Y}$ with

$$\text{fib} = \{ \text{epimorphisms with kernel in } \Phi^\perp \},$$

$$\text{cof} = \{ \text{monomorphisms with cokernel in } \perp \Psi \},$$

$$\text{weq} = \{ \text{morphisms which factor as a monomorphism with cokernel in } \mathcal{W} \text{ followed by an epimorphism with kernel in } \mathcal{W} \},$$

and the localisation $\text{weq}^{-1} \mathcal{Y}$ is triangulated.

We will give an example after recalling Gillespie’s Theorem.

0.iv. Gillespie’s Theorem: Chain complexes.

Gillespie’s Theorem gives a systematic way to construct compatible cotorsion pairs in the category of chain complexes. It requires the following setup.

- $\mathcal{M}$ is an abelian category with enough projective and enough injective objects.
- $\mathcal{C}(\mathcal{M})$ is the category of chain complexes over $\mathcal{M}$.
- For $q \in \mathbb{Z}$, consider the functors

$$\xymatrix{ \mathcal{M} \ar[r]^-{S_q} & \mathcal{C}(\mathcal{M}) \ar[r]^-{C_q} & \mathcal{C}(\mathcal{M}) }$$

where $S_q$ sends $M$ to the chain complex with $M$ in degree $q$ and zero everywhere else, and $C_q$ and $K_q$ are given by

$$C_q(X) = \text{Coker}(\partial^X_{q+1}), \quad K_q(X) = \text{Ker}(\partial^X_q).$$

Here $\partial^X_q$ is the $q$th differential of the chain complex $X$. There are adjoint pairs $(C_q, S_q)$ and $(S_q, K_q)$.

The following is Gillespie’s Theorem.

**Theorem 0.3** ([11] thm. 3.12 and cor. 3.13). If $(\mathcal{A}, \mathcal{B})$ is a hereditary cotorsion pair in $\mathcal{M}$, then there are hereditary, compatible cotorsion pairs $(\Phi(\mathcal{A}), \Phi(\mathcal{A})^\perp)$ and $(\perp \Psi(\mathcal{B}), \Psi(\mathcal{B}))$ in $\mathcal{C}(\mathcal{M})$, where

$$\Phi(\mathcal{A}) = \{ X \in \mathcal{C}(\mathcal{M}) \mid \text{If } q \in \mathbb{Z} \text{ then } C_q(X) \in \mathcal{A} \text{ and } H_q(X) = 0 \};$$

$$\Psi(\mathcal{B}) = \{ X \in \mathcal{C}(\mathcal{M}) \mid \text{If } q \in \mathbb{Z} \text{ then } K_q(X) \in \mathcal{B} \text{ and } H_q(X) = 0 \}.$$ 

For instance, the projective cotorsion pair $(\mathcal{A}, \mathcal{B}) = (\text{projective objects}, \mathcal{M})$ gives

$$(\Phi(\mathcal{A}), \Phi(\mathcal{A})^\perp) = (\mathcal{P}, \mathcal{P}^\perp), \quad (\perp \Psi(\mathcal{B}), \Psi(\mathcal{B})) = (\perp \mathcal{E}, \mathcal{E}), \quad (0.2)$$

where $\mathcal{P}$ is the class of projective objects in $\mathcal{C}(\mathcal{M})$ and $\mathcal{E}$ is the class of exact chain complexes. Note that $\mathcal{P}^\perp = \mathcal{C}(\mathcal{M})$. The cotorsion pairs $(0.2)$ are hereditary and compatible by Gillespie’s Theorem. If $\mathcal{M}$ is a complete and cocomplete category, then the cotorsion pairs $(0.2)$ are complete, and then Theorem $(0.2)$ says that they determine an abelian model category structure on $\mathcal{C}(\mathcal{M})$. The associated localisation $\text{weq}^{-1} \mathcal{C}(\mathcal{M})$ is the derived category $\mathcal{D}(\mathcal{M})$, see [9] thm. 5.3].
Our main theorem is a generalisation of Gillespie’s Theorem to quiver representations. It requires the following setup, which we keep in the rest of the introduction.

- \( k \) is a field, \( R \) is a \( k \)-algebra, \( R\text{-Mod} \) is the category of \( R \)-left-modules.
- \( Q \) is a self-injective quiver with relations over \( k \), see Paragraph 2.4.
- \( \mathcal{X} \) is the category of representations of \( Q \) with values in \( R\text{-Mod} \). If \( p \rightarrow q \) is an arrow in \( Q \), then the corresponding homomorphism in \( X \in \mathcal{X} \) is \( X_p \xrightarrow{X_{pq}} X_q \).
- For \( q \) an element of \( Q_0 \), the set of vertices of \( Q \), consider the functors

\[
\begin{align*}
C_q(-) &= DS(q) \otimes_{Q} - , \\
S_q(-) &= S(q) \otimes_{k} - , \\
K_q(-) &= \text{Hom}_Q(S(q), -).
\end{align*}
\]

Here \( S(q) \) is the simple representation of \( Q \) supported at \( q \). Its dual \( DS(q) = \text{Hom}_k(S(q), k) \) is the simple representation of the opposite quiver \( Q^\circ \) supported at \( q \). The symbols \( \otimes \) and \( \text{Hom}_Q \) denote the tensor product and homomorphism functors of representations of \( Q \). Note that \( S_q \) sends \( M \) to the representation with \( M \) at vertex \( q \) and zero everywhere else. There are adjoint pairs \((C_q, S_q)\) and \((S_q, K_q)\).

Our main theorem is the following.

**Theorem A.** If \((\mathcal{A}, \mathcal{B})\) is a hereditary cotorsion pair in \( R\text{-Mod} \), then there are hereditary, compatible cotorsion pairs \((\Phi(\mathcal{A}), \Phi(\mathcal{A})^\perp)\) and \((\Psi(\mathcal{B}), \Psi(\mathcal{B})^\perp)\) in \( \mathcal{X} \), the category of representations of \( Q \) with values in \( R\text{-Mod} \), where

\[
\begin{align*}
\Phi(\mathcal{A}) &= \{ X \in \mathcal{X} \mid \text{If } q \in Q_0 \text{ then } C_q(X) \in \mathcal{A} \text{ and } L_1 C_q(X) = 0 \}, \\
\Psi(\mathcal{B}) &= \{ X \in \mathcal{X} \mid \text{If } q \in Q_0 \text{ then } K_q(X) \in \mathcal{B} \text{ and } R^1 K_q(X) = 0 \}.
\end{align*}
\]

In the body of the paper, we prove the more general Theorem 3.2 where \( Q \) is a small \( k \)-preadditive category, and \( \mathcal{X} \) is the functor category of \( k \)-linear functors \( Q \rightarrow R\text{-Mod} \). Paragraph 2.4 explains how a quiver can be viewed as a category, whence Theorem 3.2 specialises to Theorem A.

Theorem A specialises to Gillespie’s Theorem for \( \mathcal{M} = R\text{-Mod} \) if \( Q \) is the quiver with relations from 0.1. Then \( \mathcal{X} \) is the category of chain complexes over \( R\text{-Mod} \). A computation shows that the functors \( C_q, S_q, K_q \) specialise to those of Section 0.1xiv and that

\[
L_1 C_q = H_{q+1} , \quad R^1 K_q = H_{q-1},
\]

whence the formulae in Theorem A specialise to those in Gillespie’s Theorem. However, Theorem A applies to many other quivers with relations. Following Iyama and Minamoto [18, def. 8], we then think of \( L_1 C_q \) and \( R^1 K_q \) as generalised homology functors.

To serve as the input for Theorem 0.2, the cotorsion pairs \((\Phi(\mathcal{A}), \Phi(\mathcal{A})^\perp)\) and \((\Psi(\mathcal{B}), \Psi(\mathcal{B})^\perp)\) must be complete. In the setup of Theorem 0.3, this is indeed true under the conditions that \( \mathcal{M} \) is a complete and cocomplete category and \((\mathcal{A}, \mathcal{B})\) is a complete cotorsion pair, see [7, thm. 2.4]. In the more complicated setup of Theorem A, we do not have an equally neat result, but we do prove completeness in certain cases, see Theorem 3.3.
0.vi. **Application: $N$-periodic chain complexes.**

Let $N \geq 1$ be an integer.

- In Section 0.vi only, $Q$ is the following quiver with relations.

\[
\begin{array}{c}
\text{Quiver:} \\
N - 1 \longrightarrow N - 2 \longrightarrow \cdots \longrightarrow 1 \longrightarrow 0
\end{array}
\]  

(0.3)

This is a self-injective quiver with relations, see Paragraph 2.4.

An object $X \in \mathcal{X}$ has the form

\[
X_{N-1} \xrightarrow{\partial_{N-1}^X} X_{N-2} \xrightarrow{\partial_{N-2}^X} \cdots \xrightarrow{\partial_1^X} X_1 \xrightarrow{\partial_0^X} X_0,
\]

where two consecutive morphisms compose to 0. Hence $\mathcal{X}$ is the category of $N$-periodic chain complexes over $\text{RMod}$. This even makes sense for $N = 1$, in which case $X$ is a so-called module with differentiation in the sense of [6] sec. IV.1], consisting of an object $X_0 \in \text{RMod}$ and a morphism $X_0 \xrightarrow{\partial_0^X} X_0$ squaring to 0.

For $0 \leq q \leq N - 1$ there is a homology functor $\mathcal{X} \xrightarrow{H_q} \text{RMod}$ defined in an obvious fashion. We will use our theory to prove the following.

**Theorem B.** Let $(\mathcal{A}, \mathcal{B})$ be a hereditary cotorsion pair in $\text{RMod}$.

(i) There are hereditary, compatible cotorsion pairs $(\Phi(\mathcal{A}), \Phi(\mathcal{A})^\perp)$ and $(\Psi(\mathcal{B}), \Psi(\mathcal{B})^\perp)$ in $\mathcal{X}$, the category of $N$-periodic chain complexes over $\text{RMod}$, where

\[
\Phi(\mathcal{A}) = \{ X \in \mathcal{X} | \text{If } 0 \leq q \leq N - 1 \text{ then } \text{Coker}(\partial_q^X) \in \mathcal{A} \text{ and } H_q(X) = 0 \},
\]

\[
\Psi(\mathcal{B}) = \{ X \in \mathcal{X} | \text{If } 0 \leq q \leq N - 1 \text{ then } \text{Ker}(\partial_q^X) \in \mathcal{B} \text{ and } H_q(X) = 0 \}.
\]

(ii) If $\mathcal{A}$ is closed under pure quotients and $(\mathcal{A}, \mathcal{B})$ is generated by a set, then the cotorsion pairs in part (i) are complete.

This applies to the so-called flat cotorsion pair $(\mathcal{A}, \mathcal{B}) = (\text{flat modules, cotorsion modules})$: Heredity holds by [12] thm. 8.1(a)], the class of flat modules is easily seen to be closed under pure quotients, and generation by a set holds by [5] prop. 2] (in which “cogenerated” means the same as our “generated”). Hence Theorem [13] provides an $N$-periodic version of Gillespie’s result for chain complexes from [11] (see theorem 3.12 and corollaries 3.13, 4.10, 4.18 in that paper). Theorem [12] also applies to the injective cotorsion pair $(\mathcal{A}, \mathcal{B}) = (\text{RMod, injective modules}).

0.vii. **Application: $\mathbb{Z}A_3$ with mesh relations.**

The following is a slightly more complicated example.

- In Section 0.vii only, $Q$ is the repetitive quiver $\mathbb{Z}A_3$ modulo the mesh relations. That is, $Q$ is

\[
\begin{array}{cccccc}
(3, 2) & (2, 2) & (1, 2) & (0, 2) & (-1, 2) \\
\cdots & (2, 1) & (1, 1) & (0, 1) & (-1, 1) & \cdots \\
(2, 0) & (1, 0) & (0, 0) & (-1, 0) & (-2, 0)
\end{array}
\]  

(0.4)
modulo the relations that each composition of the form \( \circ \), or \( \circ \), which starts and ends on the edge of the quiver, is zero, and that each square of the form \( \circ \) is anticommutative.

This is a self-injective quiver with relations, see Paragraph 2.

For \( j \in \mathbb{Z} \), the mesh relations imply that there are short chain complexes

\[
\begin{align*}
X_{(j,0)} &\to X_{(j,1)} \to X_{(j-1,0)}, \\
X_{(j,1)} &\to X_{(j-1,0)} \oplus X_{(j,2)} \to X_{(j-1,1)}, \\
X_{(j,2)} &\to X_{(j-1,1)} \to X_{(j-1,2)}.
\end{align*}
\]

We will use our theory to prove the following.

**Theorem C.** If \((\mathcal{A}, \mathcal{B})\) is a hereditary cotorsion pair in \( R\text{Mod} \), then there are hereditary, compatible cotorsion pairs \((\Phi(\mathcal{A}), \Phi(\mathcal{A})^\perp)\) and \((\Psi(\mathcal{B}), \Psi(\mathcal{B}))\) in \( \mathcal{X} \), the category of representations of \( Q \) with values in \( R\text{Mod} \), where

\[
\Phi(\mathcal{A}) = \begin{cases}
X \in \mathcal{X} & \text{If } j \in \mathbb{Z} \text{ then each of the following cokernels is in } \mathcal{A}: \\
& \text{Coker}(X_{(j,1)} \to X_{(j-1,0)}), \\
& \text{Coker}(X_{(j,0)} \oplus X_{(j+1,2)} \to X_{(j,1)}), \\
& \text{Coker}(X_{(j,1)} \to X_{(j,2)}), \\
& \text{and each of the short chain complexes (0.5) is exact}
\end{cases}
\]

\[
\Psi(\mathcal{B}) = \begin{cases}
X \in \mathcal{X} & \text{If } j \in \mathbb{Z} \text{ then each of the following kernels is in } \mathcal{B}: \\
& \text{Ker}(X_{(j,0)} \to X_{(j,1)}), \\
& \text{Ker}(X_{(j,1)} \to X_{(j-1,0)} \oplus X_{(j,2)}), \\
& \text{Ker}(X_{(j,2)} \to X_{(j-1,1)}), \\
& \text{and each of the short chain complexes (0.5) is exact}
\end{cases}
\]

0.viii. **Other self-injective quivers with relations.**

There are many other self-injective quivers with relations to which Theorem A can be applied, for instance \( \cdots \to 2 \to 1 \to 0 \to -1 \to -2 \to \cdots \) with the relations that \( N \) consecutive arrows compose to 0. Then \( \mathcal{X} \) is the category of \( N \)-complexes over \( R\text{Mod} \) in the sense of [20] def. 0.1. Other possibilities are \( \mathbb{Z}A_n \) with mesh relations, the quiver with relations of a finite dimensional self-injective \( k \)-algebra, and quivers with relations of repetitive algebras, see [22] sec. 3.1 and [29] sec. 2.

0.ix. **An observation on the model category literature.**

Observe that Theorem A does not assume the existence of a model category structure on \( R\text{Mod} \). This is in contrast to several results from the literature, where a model category structure on a functor category \( \text{Fun}(\mathcal{I}, \mathcal{M}) \) is induced by a model category structure on \( \mathcal{M} \). If \( \mathcal{I} \) is a small category, then such results exist when \( \mathcal{M} \) has a cofibrantly generated or combinatorial model category structure, see [13] thm. 11.6.1 and [23] prop. A.2.8.2, and when \( \mathcal{M} \) has an arbitrary model category structure and \( \mathcal{I} \) is a direct, an inverse, or a Reedy category, see [16] thms. 5.1.3 and 5.2.5.
0.x. Contents of the paper.

Section 1 defines the cotorsion pairs \((\Phi(A), \Phi(A)\perp)\) and \((\perp \Psi(B), \Psi(B))\) in an abstract setup, and shows that they are hereditary and compatible under certain assumptions. Section 2 introduces functor categories. Section 3 proves Theorem 3.2, which has Theorem A as a special case. Sections 4, 5, and 6 provide several results used in the proof of Theorem 3.2. Section 7 proves Theorem B. Section 8 proves Theorem C. Appendix A provides additional background on functor categories.

1. The cotorsion pairs \((\Phi(A), \Phi(A)\perp)\) and \((\perp \Psi(B), \Psi(B))\) in an abstract setup

This section defines the cotorsion pairs \((\Phi(A), \Phi(A)\perp)\) and \((\perp \Psi(B), \Psi(B))\) in an abstract setup, and shows that they are hereditary and compatible under certain assumptions.

Setup 1.1. Section 1 uses the following setup.

- \(\mathcal{M}\) and \(\mathcal{X}\) are abelian categories with enough projective and enough injective objects.
- \((\mathcal{A}, \mathcal{B})\) is a cotorsion pair in \(\mathcal{M}\).
- \(J\) is an index set.
- For each \(j \in J\) there are adjoint pairs of functors \((C_j, S_j)\) and \((S_j, K_j)\) as follows.

\[
\begin{array}{c}
\mathcal{M} \\
\downarrow \downarrow \\
\mathcal{X} \\
\uparrow \uparrow \\
\mathcal{X} \\
\end{array}
\]

\(C_j\) \quad \(S_j\) \quad \(K_j\)

Note that this implies that \(S_j\) is exact.

The following lemma provides a so-called “five term exact sequence”. It is classic, but we show the proof because we do not have a reference for the precise statement.

Lemma 1.2. Let \((C, S)\) be an adjoint pair of functors as follows: \(\mathcal{M} \xrightarrow{C} \mathcal{X}\). Assume that \(S\) is exact. For \(N \in \mathcal{M}\) and \(X \in \mathcal{X}\) there is an exact sequence

\[
0 \to \Ext^1_M(CX, N) \to \Ext^1_N(X, SN) \to \Hom_M(L_1CX, N) \to \Ext^2_M(CX, N) \to \Ext^2_N(X, SN).
\]

Proof. Consider the functors \(\mathcal{X} \xrightarrow{C} \mathcal{M} \xrightarrow{B} \mathcal{Ab}\) where \(\mathcal{Ab}\) is the category of abelian groups and \(B(\cdot) = \Hom_M(\cdot, N)\).

The contravariant functor \(B\) is left exact. If \(P \in \mathcal{X}\) is projective, then \(C(P) \in \mathcal{M}\) is projective because \(\Hom_M(CP, \cdot) \cong \Hom_\mathcal{X}(P, S(\cdot))\) is an exact functor since \(S\) is exact. In particular, the functor \(C\) maps projective objects to right \(B\)-acyclic objects, that is, objects on which the derived functors \(R^{\geq 1}B\) vanish.

By [27, thm. 10.49] there is a Grothendieck third quadrant spectral sequence

\[
E_2^{ij} = (R^iB)(L_iC)X \Rightarrow R^n(BC)X.
\]

If \(P\) is a projective resolution of \(X\), then

\[
R^n(BC)X \cong H^n(BCP) = H^n\Hom_M(CP, N) \cong H^n\Hom_\mathcal{X}(P, SN) \cong \Ext^n_\mathcal{X}(X, SN).
\]

Hence the spectral sequence is

\[
E_2^{ij} = \Ext^i_M(L_iCX, N) \Rightarrow \Ext^n_\mathcal{X}(X, SN).
\]
By [27, thm. 10.33] there is an associated exact sequence, which gives the sequence in the lemma.

We record the dual without a proof:

**Lemma 1.3.** Let \((S, K)\) be an adjoint pair of functors as follows: \(\mathcal{M} \xrightarrow{S} \mathcal{X}\). Assume that \(S\) is exact. For \(N \in \mathcal{M}\) and \(X \in \mathcal{X}\) there is an exact sequence

\[0 \to \text{Ext}^1_{\mathcal{M}}(N, KX) \to \text{Ext}^1_{\mathcal{X}}(SN, X) \to \text{Hom}_{\mathcal{M}}(N, R^1KX) \to \text{Ext}^2_{\mathcal{M}}(N, KX) \to \text{Ext}^2_{\mathcal{X}}(SN, X).\]

The following is well known.

**Lemma 1.4.** A cotorsion pair \((\mathcal{A}, \mathcal{B})\) in \(\mathcal{M}\) is hereditary if and only if \(\mathcal{A}\) is resolving, that is, contains the projective objects and is closed under kernels of epimorphisms.

**Proof.** See [12, lem. 5.24], the proof of which works in the present generality.

**Definition 1.5.** Let

\[\mathcal{E}_L = \{ X \in \mathcal{X} \mid \text{If } j \in J \text{ then } L_1C_j(X) = 0 \},\]

\[\mathcal{E}_R = \{ X \in \mathcal{X} \mid \text{If } j \in J \text{ then } R^1K_j(X) = 0 \}.\]

If \(\mathcal{C}\) is a class of objects in \(\mathcal{M}\), then let

\[\Phi(\mathcal{C}) = \{ X \in \mathcal{X} \mid \text{If } j \in J \text{ then } C_j(X) \in \mathcal{C} \text{ and } L_1C_j(X) = 0 \},\]

\[\Psi(\mathcal{C}) = \{ X \in \mathcal{X} \mid \text{If } j \in J \text{ then } K_j(X) \in \mathcal{C} \text{ and } R^1K_j(X) = 0 \}.\]

Note that \(\Phi(\mathcal{C}) \subseteq \mathcal{E}_L\) and \(\Psi(\mathcal{C}) \subseteq \mathcal{E}_R\).

If \(\mathcal{C}\) is a class of objects in \(\mathcal{M}\), then we use the shorthand \(\{ S_{s}(\mathcal{C}) \} = \{ S_j(C) \mid j \in J, C \in \mathcal{C} \}\).

**Lemma 1.6.** Let \(\mathcal{C}\) be a class of objects in \(\mathcal{M}\).

(i) Assume that for each non-zero \(M \in \mathcal{M}\) there is an injective object \(I\) which is in \(\mathcal{C}\) and satisfies \(\text{Hom}_{\mathcal{M}}(M, I) \neq 0\). Then \(\Phi(\mathcal{C}) = \{ \{ S_s(\mathcal{C}) \} \}^\perp\).

(ii) Assume that for each non-zero \(M \in \mathcal{M}\) there is a projective object \(P\) which is in \(\mathcal{C}\) and satisfies \(\text{Hom}_{\mathcal{M}}(P, M) \neq 0\). Then \(\Psi(\mathcal{C})^\perp = \{ \{ S_s(\mathcal{C}) \} \}^\perp\).

**Proof.** First note that for \(N \in \mathcal{C}, X \in \mathcal{X}, j \in J\), there is an exact sequence

\[0 \to \text{Ext}^1_{\mathcal{M}}(C_jX, N) \to \text{Ext}^1_{\mathcal{X}}(X, S_jN) \to \text{Hom}_{\mathcal{M}}(L_1C_jX, N) \to \text{Ext}^2_{\mathcal{M}}(C_jX, N)\]  

(1.1) by Lemma 1.2.

Part (i), the inclusion \(\subseteq\): Let \(X \in \Phi(\mathcal{C})^\perp\) and \(j \in J\) be given. Then \(C_j(X) \in \mathcal{C}\) and \(L_1C_j(X) = 0\) by the definition of \(\Phi\). It follows that for \(N \in \mathcal{C}\), the terms in (1.1) which involve \(\text{Ext}^1_{\mathcal{M}}\) and \(\text{Hom}_{\mathcal{M}}\) are 0, so (1.1) implies \(\text{Ext}^1_{\mathcal{X}}(X, S_jN) = 0\). Hence \(X \in \{ \{ S_s(\mathcal{C}) \} \}^\perp\).

Part (i), the inclusion \(\supseteq\): Let \(X \in \{ \{ S_s(\mathcal{C}) \} \}^\perp\) and \(j \in J\) be given.

For \(N \in \mathcal{C}\), the term in (1.1) which involves \(\text{Ext}^1_{\mathcal{X}}\) is 0, so (1.1) implies \(\text{Ext}^1_{\mathcal{M}}(C_jX, N) = 0\). Hence \(C_j(X) \in \mathcal{C}\).

Assume that \(L_1C_j(X) \neq 0\). Pick an injective object \(N\) which is in \(\mathcal{C}\) and satisfies \(\text{Hom}_{\mathcal{M}}(L_1C_jX, N) \neq 0\). By the previous paragraph, the term in (1.1) which involves \(\text{Ext}^1_{\mathcal{X}}\) is 0. However, the term involving \(\text{Ext}^2_{\mathcal{M}}\) is also 0 since \(N\) is injective, so (1.1) implies \(\text{Hom}_{\mathcal{M}}(L_1C_jX, N) = 0\). This is a contradiction, so we conclude \(L_1C_j(X) = 0\). Combining with the previous paragraph shows \(X \in \Phi(\mathcal{C})^\perp\).

Part (ii): Proved dually to part (i).
Theorem 1.7. There are cotorsion pairs \((\Phi(\mathcal{A}), \Phi(\mathcal{A})^\perp)\) and \((\perp \Psi(\mathcal{B}), \Psi(\mathcal{B}))\) in \(\mathcal{X}\).

Proof. The class \(\mathcal{A}\) contains the projective objects of \(\mathcal{M}\), and the class \(\mathcal{B}\) contains the injective objects of \(\mathcal{M}\). Since we also have \(\mathcal{A} = \perp \mathcal{B}\) and \(\mathcal{B} = \mathcal{A}^\perp\), Lemma \[1.6\] implies
\[
\Phi(\mathcal{A}) = \perp \{S_*(\mathcal{B})\}, \quad \Psi(\mathcal{B}) = \{S_*(\mathcal{A})\}^\perp.
\]
Hence there are the following cotorsion pairs, see [12, def. 5.15]:
\[
(\Phi(\mathcal{A}), \Phi(\mathcal{A})^\perp) = (\perp \{S_*(\mathcal{B})\}, \{S_*(\mathcal{A})\}^\perp),
\]
\[
(\perp \Psi(\mathcal{B}), \Psi(\mathcal{B})) = (\{S_*(\mathcal{A})\}^\perp, \{S_*(\mathcal{A})\}^\perp).
\]
\(\square\)

Theorem 1.8. Assume that \((\mathcal{A}, \mathcal{B})\) is a hereditary cotorsion pair in \(\mathcal{M}\).

(i) If \(L_2C_j(\mathcal{E}_L) = 0\) for \(j \in J\), then there is a hereditary cotorsion pair \((\Phi(\mathcal{A}), \Phi(\mathcal{A})^\perp)\) in \(\mathcal{X}\).

(ii) If \(R_2K_j(\mathcal{E}_R) = 0\) for \(j \in J\), then there is a hereditary cotorsion pair \((\perp \Psi(\mathcal{B}), \Psi(\mathcal{B}))\) in \(\mathcal{X}\).

Proof. The cotorsion pairs exist by Theorem \[1.7\] and we must prove heredity under the given assumptions.

(i): Lemma \[1.4\] implies that \(\mathcal{A}\) is resolving, and that it is enough to prove that so is \(\Phi(\mathcal{A})\). Let \(0 \to X' \to X \to X'' \to 0\) be a short exact sequence in \(\mathcal{X}\) with \(X, X'' \in \Phi(\mathcal{A})\), and let \(j \in J\) be given. By definition we have \(C_j(X), C_j(X'') \in \mathcal{A}\) and \(L_1C_j(X) = L_1C_j(X'') = 0\). In particular, \(X'' \in \mathcal{E}_L\), so the assumption in part (i) says \(L_2C_j(X'') = 0\). Hence the long exact sequence
\[
\cdots \to L_2C_j(X'') \to L_1C_j(X') \to L_1C_j(X) \to L_1C_j(X'') \to C_j(X') \to C_j(X) \to C_j(X'') \to 0
\]
reads
\[
\cdots \to 0 \to L_1C_j(X') \to 0 \to 0 \to C_j(X') \to C_j(X) \to C_j(X'') \to 0.
\]
This implies \(L_1C_j(X') = 0\). It also implies \(C_j(X') \in \mathcal{A}\) because \(\mathcal{A}\) is resolving and \(C_j(X), C_j(X'') \in \mathcal{A}\). Hence \(X' \in \Phi(\mathcal{A})\) as desired.

(ii): Proved dually to (i). \(\square\)

Definition 1.9. Consider the following conditions on the classes \(\mathcal{E}_L, \mathcal{E}_R, \Phi(\mathcal{A}), \Psi(\mathcal{B})\) from Definition \[1.5\]

(Ex) \(\mathcal{E}_L = \mathcal{E}_R\).

(Seq) If \(j \in J\) is given, then:

(i) Each \(A \in \mathcal{A}\) permits a short exact sequence in \(\mathcal{X}\),
\[
0 \to S_j(A) \to R \to U \to 0,
\]
with \(R \in \Phi(\mathcal{A})\) and \(\text{Ext}^2_{\mathcal{X}}(U, \mathcal{E}_R) = 0\).

(ii) Each \(B \in \mathcal{B}\) permits a short exact sequence in \(\mathcal{X}\),
\[
0 \to W \to T \to S_j(B) \to 0,
\]
with \(T \in \Psi(\mathcal{B})\) and \(\text{Ext}^2_{\mathcal{X}}(\mathcal{E}_L, W) = 0\).

Remark 1.10. It is not obvious that the sequences in condition (Seq) of the definition exist. Their construction in the category of representations of a self-injective quiver is a key technical part of the paper, see Section \[6\].

Theorem 1.11. Assume that conditions (Comp1), (Ex), and (Seq) hold (see Definitions \[0.7\] and \[1.9\]). Then there are compatible cotorsion pairs \((\Phi(\mathcal{A}), \Phi(\mathcal{A})^\perp)\) and \((\perp \Psi(\mathcal{B}), \Psi(\mathcal{B}))\) in \(\mathcal{X}\).
Proof. The cotorsion pairs exist by Theorem 1.7, and we must prove that they are compatible under the given assumptions, which amounts to proving that condition (Comp2) holds. We have assumed condition (Ex), so write $\mathcal{E} = \mathcal{E}_L = \mathcal{E}_R$. It is enough to prove
\begin{align}
\Phi(\mathcal{A}) \cap \mathcal{E} & = \Phi(\mathcal{A}), \\
\Phi(\mathcal{A})^\perp \cap \mathcal{E} & = \Psi(\mathcal{B}),
\end{align}
(1.2) (1.3)
since then
$$\Phi(\mathcal{A}) \cap \Phi(\mathcal{A})^\perp \cap \mathcal{E} = \Phi(\mathcal{A}) \cap \Psi(\mathcal{B}) = \Phi(\mathcal{A}) \cap \Psi(\mathcal{B}) \cap \mathcal{E},$$
and this shows (Comp2) since $\mathcal{E}$ can be removed from the displayed formula because $\Phi(\mathcal{A}), \Psi(\mathcal{B}) \subseteq \mathcal{E}$.

We prove Equation (1.2) by establishing the two inclusions.

The inclusion $\subseteq$: Let $X \in \Phi(\mathcal{B}) \cap \mathcal{E}$ be given. Given $j \in J$ and $B \in \mathcal{B}$, condition (Seq)(ii) provides a short exact sequence in $\mathcal{X}$,
$$0 \to W \to T \to S_j(B) \to 0,$$
with $T \in \Psi(\mathcal{B})$ and $\Ext^2_{\mathcal{X}}(\mathcal{E}, W) = 0$. There is a long exact sequence containing
$$\Ext^1_{\mathcal{X}}(X, T) \to \Ext^1_{\mathcal{X}}(X, S_j B) \to \Ext^2_{\mathcal{X}}(X, W).$$
The first term is zero since $X \in \Phi(\mathcal{B})$ and $T \in \Psi(\mathcal{B})$. The last term is zero since $X \in \mathcal{E}$ and $\Ext^2_{\mathcal{X}}(\mathcal{E}, W) = 0$. Hence the middle term is zero: $\Ext^1_{\mathcal{X}}(X, S_j B) = 0$. By Lemma 1.12 this implies $\Ext^1_{\mathcal{X}}(C_j X, B) = 0$ whence $C_j(X) \in \Phi(\mathcal{A})$. We also know $X \in \mathcal{E}$, so $L_1 C_j(X) = 0$. It follows that $X \in \Phi(\mathcal{A})$.

The inclusion $\supseteq$: This follows because $\Phi(\mathcal{A}) \subseteq \mathcal{E}$, while condition (Comp1) implies $\Phi(\mathcal{A}) \subseteq \Phi(\mathcal{B})$. Equation (1.3) is proved dually to Equation (1.2).

We end by recording a lemma which has almost the same proof as Theorem 1.7.

**Lemma 1.12.** Let $\mathcal{C}$ be a class of objects in $\mathcal{M}$.

(i) Assume that for each non-zero $M \in \mathcal{M}$ there is an injective object $I$ which is in $\mathcal{C}$ and satisfies $\Hom_{\mathcal{M}}(M, I) \neq 0$.

If $(\mathcal{A}, \mathcal{B})$ is the cotorsion pair in $\mathcal{M}$ cogenerated by $\mathcal{C}$, then $(\Phi(\mathcal{A}), \Phi(\mathcal{A})^\perp)$ is the cotorsion pair in $\mathcal{X}$ cogenerated by $\{ S_*(\mathcal{C}) \}$.

(ii) Assume that for each non-zero $M \in \mathcal{M}$ there is a projective object $P$ which is in $\mathcal{C}$ and satisfies $\Hom_{\mathcal{M}}(P, M) \neq 0$.

If $(\mathcal{A}, \mathcal{B})$ is the cotorsion pair in $\mathcal{M}$ generated by $\mathcal{C}$, then $(\Phi(\mathcal{B}), \Psi(\mathcal{B}))$ is the cotorsion pair in $\mathcal{X}$ generated by $\{ S_*(\mathcal{C}) \}$.

**Proof.** (i): If $(\mathcal{A}, \mathcal{B})$ is cogenerated by $\mathcal{C}$, then $\mathcal{A} = \Phi(\mathcal{A})^\perp$, so Lemma 1.6 implies $\Phi(\mathcal{A}) = (\Phi(\mathcal{A})^\perp)^\perp = (\{ S_*(\mathcal{C}) \})^\perp$.

Hence
$$\Phi(\mathcal{A}) \cap \mathcal{E} = (\{ S_*(\mathcal{C}) \} \cap (\{ S_*(\mathcal{C}) \})^\perp)$$
is the cotorsion pair cogenerated by $\{ S_*(\mathcal{C}) \}$.

(ii) is proved dually to (i).
2. Functor categories

This section introduces functor categories. In particular, Paragraph 2.4 explains how a category of quiver representations can be viewed as a functor category, whence Theorem 3.2 has Theorem A as a special case.

**Setup 2.1.** Section 2 uses the following setup.

- $k$ is a field.
- $R$ is a $k$-algebra.

2.2 (Functor categories). Let $Q$ be a small $k$-preadditive category; that is, each Hom-space is a $k$-vector space and composition of morphisms is $k$-bilinear. The homomorphism functor and the radical of $Q$ will be denoted $Q(-,-)$ and $\text{rad}Q(-,-)$, see [1 sec. A.3], [8 sec. 3.2], and [21, p. 303].

Let $Q^o$ denote the opposite category, and let $k\text{Mod}$ and $R\text{Mod}$ denote, respectively, the categories of $k$-vector spaces and $R$-left-modules. There are the following functor categories.

- $Q\text{Mod} = \text{the category of } k\text{-linear functors } Q \to k\text{Mod}$
- $\text{Mod}_Q = \text{the category of } k\text{-linear functors } Q^o \to k\text{Mod}$
- $Q,R\text{Mod} = \text{the category of } k\text{-linear functors } Q \to R\text{Mod}$
- $Q\text{Mod}_Q = \text{the category of } k\text{-linear functors } Q^o \times Q \to k\text{Mod}$

Their homomorphism functors are denoted $\text{Hom}_Q$, $\text{Hom}_{Q^o}$, $\text{Hom}_{Q,R}$, and $\text{Hom}_{Q^o}$.

We think of them as the categories of $Q$-left-modules, $Q$-right-modules, $Q$-left-$R$-left-modules, and $Q$-bi-modules. They are abelian categories with enough projective and injective objects, which are in fact Grothendieck categories. In each of the categories $Q\text{Mod}$, $\text{Mod}_Q$, and $Q,R\text{Mod}$, a sequence of functors $L' \xrightarrow{\lambda} L \xrightarrow{\lambda} L''$ is short exact if $0 \to L'(q) \xrightarrow{\lambda} L(q) \xrightarrow{\lambda} L''(q) \to 0$ is a short exact sequence in $Q\text{Mod}$ or $R\text{Mod}$ for each $q \in Q$. An object $X$ of $Q,R\text{Mod}$ can be viewed as an object of $Q\text{Mod}$ by forgetting the $R$-structure on each $X(q)$ for $q \in Q$. We refer to Appendix A for additional information.

**Definition 2.3.** The following are conditions we can impose on a small $k$-preadditive category $Q$.

- **(Fin)** Each Hom-space of $Q$ is finite dimensional over $k$. If $q \in Q$ is fixed then $Q(p,q) = Q(q,p) = 0$ except for finitely many $p \in Q$. There is an integer $N$ such that $\text{rad}^N_Q = 0$.
- **(Rad)** If $q \in Q$ then $Q(q,q)$ is a local $k$-algebra, and the canonical map $k \to Q(q,q)/\text{rad}Q(q,q)$ is an isomorphism of $k$-algebras. If $p \neq q$ are in $Q$ then $Q(p,q) = \text{rad}Q(p,q)$.
- **(SelfInj)** The category $Q$ has a Serre functor, that is, a $k$-linear autoequivalence $W : Q \to Q$ such that there are natural isomorphisms $Q(p,q) \cong DQ(q,Wp)$ where $D(-) = \text{Hom}_k(-,k)$.

Note that the last part of condition (Rad) implies that different objects of $Q$ are non-isomorphic. Conditions (Fin) and (Rad) imply that $Q$ is a locally bounded spectroid in the terminology of [8 secs. 3.5 and 8.3], whence the functor categories over $Q$ share many properties of module categories over a finite dimensional algebra, see Appendix A. If condition (SelfInj) also holds, then projective, injective, and flat objects coincide in each of $Q\text{Mod}$ and $Q,R\text{Mod}$, see Paragraph A.6.

2.4 (Special case: Quivers with relations). Let $Q$ be a quiver with relations over $k$ in the sense of [1 def. II.2.3]. Then $Q$ can be viewed as a small $k$-preadditive category: The objects are the vertices, and the morphism spaces are the $k$-linear combinations of paths modulo relations. Composition of morphisms is induced by concatenation of paths.

Viewed as a quiver with relations, $Q$ has a category $\mathcal{X}$ of representations with values in $R\text{Mod}$. Viewed as a small $k$-preadditive category, $Q$ has the functor category $Q,R\text{Mod}$. The categories $\mathcal{X}$ and $Q,R\text{Mod}$ can be identified.
Structures over the category $Q$ & Structures over the algebra $\Lambda$

- $Q_{, R}\text{Mod}$ & $\Lambda_{, R}\text{Mod} = \Lambda$-left-$R$-left-modules
- $Q\text{Mod}$ & $\Lambda\text{Mod} = \Lambda$-left-modules
- $\text{Mod}_Q$ & $\text{Mod}_\Lambda = \Lambda$-right-modules
- $Q\text{Mod}_Q$ & $\Lambda\text{Mod}_\Lambda = \Lambda$-bimodules
- $\text{Hom}_{Q, R}$ & $\text{Hom}_{\Lambda, R} = \text{homomorphisms of } \Lambda$-left-$R$-left-modules
- $\text{Hom}_Q$ & $\text{Hom}_\Lambda = \text{homomorphisms of } \Lambda$-left-modules
- $\text{Hom}_{Q_\omega}$ & $\text{Hom}_{\Lambda_\omega} = \text{homomorphisms of } \Lambda$-right-modules
- $\text{Hom}_{Q_e}$ & $\text{Hom}_{\Lambda_e} = \text{homomorphisms of } \Lambda$-bimodules
- $\otimes_Q$ & $\otimes = \text{tensor product of } \Lambda$-modules
- $\otimes_k$ & $\otimes = \text{tensor product of } k$-vector spaces
- $S\langle q \rangle$ & $S\langle q \rangle = \text{the simple } \Lambda$-left-module supported at vertex $q$
- $D S\langle q \rangle$ & $D S\langle q \rangle = \text{the simple } \Lambda$-right-module supported at vertex $q$

**Figure 1.** A finite self-injective quiver with relations $Q$ can be viewed as a small $k$-preadditive category. On the other hand, it gives a finite dimensional algebra $\Lambda$, and structures over $Q$ and $\Lambda$ can be identified as shown.

We say that $Q$ is a **self-injective quiver with relations** if $Q$, viewed as a small $k$-preadditive category, satisfies conditions (Fin), (Rad), and (SelfInj) of Definition 2.3.

The quivers with relations from the introduction are self-injective. In particular, the Serre functors are given as follows: For (0.1) by the shift $q \mapsto q - 1$, for (0.3) by the shift $q \mapsto q - 1$ where $q$ is taken modulo $N$, and for (0.4) by reflecting in a horizontal line through the vertices $(1, j)$, then shifting one vertex to the right.

### 2.5 (Special case: Finite quivers with relations)

Let $Q$ be a self-injective quiver with relations over $k$. Assume that $Q$ is finite and connected, and that its relations are given by an admissible ideal $a$ in the path algebra $A$ over $k$, see [1, def. II.2.1].

On the one hand, $Q$ can be viewed as a small $k$-preadditive category, which has the functor category $Q_{, R}\text{Mod}$. On the other hand, there is a finite dimensional algebra $\Lambda = A/\mathfrak{a}$, which has the category $\Lambda_{, R}\text{Mod}$ of $\Lambda$-left-$R$-left-modules. The categories $Q_{, R}\text{Mod}$ and $\Lambda_{, R}\text{Mod}$ can be identified.

A more extensive list of identifications is given in Figure 1, where the entries in the first column are explained in Paragraph 2.2 and Appendix A. The list can be extended with Ext- and Tor-functors.

Note that since $Q$ is a self-injective quiver with relations, $\Lambda$ is a self-injective algebra.

#### 3. Proof of Theorem $\Lambda$

This section proves Theorem 3.2, which has Theorem $\Lambda$ as a special case, see Paragraph 2.4.

Sections 3 through 6 are phrased in the language of functor categories over a small $k$-preadditive category $Q$. A reader who prefers modules instead of functors can use Figure 1 to specialise everything to the case of modules over a finite dimensional self-injective algebra $\Lambda$.

**Setup 3.1.** Sections 3 through 6 use the following setup, which dovetails with Setups 1.1 and 2.1, so the results of Sections 1 and 2 can be used verbatim. We refer to Appendix A for additional
information, in particular on several functors which will be used extensively: \( \otimes_k, \text{Hom}_k, \otimes_Q, \text{Tor}_i^Q, \text{Hom}_Q, \text{Ext}^i_Q, \text{Hom}_{Q,R}, \text{Ext}^i_{Q,R} \).

- \( k \) is a field.
- \( R \) is a \( k \)-algebra.
- \( Q \) is a small \( k \)-preadditive category satisfying conditions (Fin), (Rad), and (SelfInj) of Definition 2.3.
- \( \mathcal{M} = R \text{Mod} \) is the category of \( R \)-left-modules.
- \( \mathcal{X} = Q,R \text{Mod} \) is the category of \( k \)-linear functors \( Q \to R \text{Mod} \).

The categories \( \mathcal{M} \) and \( \mathcal{X} \) have enough projective and enough injective objects by Paragraph A.4.

- \( (\mathcal{A}, \mathcal{B}) \) is a cotorsion pair in \( \mathcal{M} \).
- \( J = \text{obj} Q \). The statement \( q \in \text{obj} Q \) will be abbreviated \( q \in Q \).
- For each \( q \in Q \), there is a simple object \( DS\langle q \rangle \in \text{Mod}_Q \) and a simple object \( S\langle q \rangle \in Q \text{Mod} \), see Paragraph A.4(i). The functors

\[
\begin{align*}
C_q(\cdot) &= DS\langle q \rangle \otimes_Q \cdot, \\
S_q(\cdot) &= S\langle q \rangle \otimes_k \cdot, \\
K_q(\cdot) &= \text{Hom}_Q(S\langle q \rangle, \cdot).
\end{align*}
\tag{3.1}
\]

There is an adjoint pair \( (C_q, S_q) \) by Paragraph A.2(ii) and the observation that we have \( S_q(\cdot) = \text{Hom}_k(DS\langle q \rangle, \cdot) \) by Paragraph A.2(vi). There is an adjoint pair \( (S_q, K_q) \) by Paragraph A.2(i).

- \( \mathcal{E} \) denotes either \( \mathcal{E}_L \) or \( \mathcal{E}_R \); these classes are equal because condition (Ex) of Definition 1.9 holds by Proposition 4.2.

**Theorem 3.2.** If \( (\mathcal{A}, \mathcal{B}) \) is a hereditary cotorsion pair in \( \mathcal{M} = R \text{Mod} \), then there are hereditary, compatible cotorsion pairs \( (\Phi(\mathcal{A}), \Phi(\mathcal{A})^\perp) \) and \( (\perp \Psi(\mathcal{B}), \Psi(\mathcal{B})) \) in \( \mathcal{X} = Q,R \text{Mod} \), where

\[
\begin{align*}
\Phi(\mathcal{A}) &= \{ X \in \mathcal{X} \mid \text{If } q \in Q \text{ then } C_q(X) \in \mathcal{A} \text{ and } L_1C_q(X) = 0 \}, \\
\Psi(\mathcal{B}) &= \{ X \in \mathcal{X} \mid \text{If } q \in Q \text{ then } K_q(X) \in \mathcal{B} \text{ and } R_1K_q(X) = 0 \}.
\end{align*}
\]

**Proof.** The formulae for \( \Phi(\mathcal{A}) \) and \( \Psi(\mathcal{B}) \) are those of Definition 1.5 adapted to the present setup, so the results of Section 1 apply. In particular, the cotorsion pairs exist by Theorem 1.7. They are hereditary by Theorem 1.8 combined with Proposition 4.2 below. They are compatible by Theorem 1.11 combined with Propositions 4.2, 5.2, and 6.18 below. \( \square \)

**Theorem 3.3.** We have:

(i) If the cotorsion pair \( (\mathcal{A}, \mathcal{B}) \) is generated by a set, then the cotorsion pair \( (\perp \Psi(\mathcal{B}), \Psi(\mathcal{B})) \) is complete.
(ii) Assume that $Q$ arises from the special case described in Paragraph 2.5, so corresponds to a finite dimensional self-injective $k$-algebra $\Lambda$. If $\mathcal{A}$ is closed under pure quotients, then the cotorsion pair $(\Phi(\mathcal{A}), \Phi(\mathcal{A})^\perp)$ is complete.

Proof. (i) Suppose that $\mathcal{C}$ is a set of objects of $\mathcal{M}$ which generates $(\mathcal{A}, \mathcal{B})$. This is still the case after adding the projective $R$-left-module $R R$ to $\mathcal{C}$. Then Lemma 1.2(ii) says that $\{S_n(\mathcal{C})\}$ is a set of objects of $\mathcal{X}$ which generates $(\perp \Psi(\mathcal{B}), \Psi(\mathcal{B}))$. This cotorsion pair is hence complete by Lemma 5.20 and 30, def. 3.11, prop. 3.13, and prop. 5.8. Note that the proof of Lemma 5.20 goes through for $\mathcal{X}$ because it has enough projective objects and enough injective objects by Paragraph A.4.

(ii) As explained in Paragraph 2.5, we can view $(\Phi(\mathcal{A}), \Phi(\mathcal{A})^\perp)$ as a cotorsion pair in $\Lambda \otimes R$Mod, the category of left-modules over the $k$-algebra $\Lambda \otimes R$, which will be denoted simply by $\Lambda \otimes R$. By Lemma 5.13(b) and Lemma 5.20 and 14, thm. 2.5 it is enough to show that $\Phi(\mathcal{A})$ is closed under pure quotients.

Let $\sigma = 0 \to X' \to X \to X'' \to 0$ be pure short exact in $\Lambda \otimes R$Mod with $X \in \Phi(\mathcal{A})$. We will show $X'' \in \Phi(\mathcal{A})$, that is, $C_q(X'') \in \mathcal{A}$ and $L_1 C_q(X'') = 0$ for each $q \in Q$.

Given $q \in Q$ and $B \in \text{Mod}_R$ we have that $B \otimes C_q(\sigma) = B \otimes (DS(q) \otimes \Lambda) = (B \otimes DS(q)) \otimes \Lambda \otimes R$ is exact, because $\sigma$ is pure short exact in $\Lambda \otimes R$Mod. The isomorphism is by Lemma IX.2.1. Hence $C_q(\sigma) = 0 \to C_q(X') \to C_q(X) \to C_q(X'') \to 0$ is pure short exact in $R$Mod. But $X \in \Phi(\mathcal{A})$ implies $C_q(X) \in \mathcal{A}$ whence $C_q(X'') \in \mathcal{A}$ since $\mathcal{A}$ is closed under pure quotients.

Given $M \in \text{Mod}_\Lambda$ we have that $M \otimes \sigma \cong M \otimes ((\Lambda \otimes R) \otimes \Lambda) \otimes (\Lambda \otimes R)$ is exact, because $\sigma$ is pure short exact in $\Lambda \otimes R$Mod. Hence $\sigma$, viewed as a sequence of $\Lambda$-left-modules, is pure short exact. But $X \in \Phi(\mathcal{A})$ implies $X \in \mathcal{B}$, so $X$, viewed as a $\Lambda$-left-module, is flat by Proposition 1.2. It follows that $X''$, viewed as a $\Lambda$-left-module, is flat, so $L_1 C_q(X'') = 0$. \[\Box\]

We end this section with a description of the trivial objects in the model category structure on $\mathcal{X}$ provided by Theorems 0.2 and 3.2. We thank an anonymous referee for drawing attention to this question.

Theorem 3.4. If $(\mathcal{A}, \mathcal{B})$ is a hereditary cotorsion pair in $\mathcal{M} = \text{Mod}_R$, and either of the cotorsion pairs $(\Phi(\mathcal{A}), \Phi(\mathcal{A})^\perp)$ and $(\perp \Psi(\mathcal{B}), \Psi(\mathcal{B}))$ of Theorem 1.2 is complete (see Theorem 3.3), then the class $\mathcal{W}$ of trivial objects (defined in Theorem 0.2) satisfies $\mathcal{W} = \mathcal{E}$.

Proof. The inclusion $\mathcal{W} \subseteq \mathcal{E}$: By the first part of the first formula of Theorem 0.2, each $W \in \mathcal{W}$ sits in a short exact sequence $0 \to P \to F \to W \to 0$ in $\mathcal{X}$ with $P \in \Psi(\mathcal{B})$, $F \in \Phi(\mathcal{A})$. We have $P, F \in \mathcal{E}$ by Definition 1.5. By Proposition 1.2 this means that $P$ and $F$ are injective when viewed as objects of $\text{QMod}_R$. The same is hence true for $W$, so $W \in \mathcal{E}$ by Proposition 1.2 again.

The inclusion $\mathcal{W} \supseteq \mathcal{E}$: First, suppose $(\Phi(\mathcal{A}), \Phi(\mathcal{A})^\perp)$ is complete. Given $E \in \mathcal{E}$ there is a short exact sequence $0 \to Q \to F \to E \to 0$ in $\mathcal{X}$ with $Q \in \Phi(\mathcal{A})^\perp$, $F \in \Phi(\mathcal{A})$. By the first part of the first formula of Theorem 0.2 it is enough to show $Q \in \Psi(\mathcal{B})$. We have $F \in \mathcal{E}$ by Definition 1.5. Proposition 1.2 says that $F$ and $E$ are projective when viewed as objects of $\text{QMod}_R$. The same is hence
true for $Q$, so $Q \in \mathcal{E}$ by Proposition 4.2 again. Hence $Q \in \Phi(\mathcal{A}) \cap \mathcal{E}$. It follows that, as desired, $Q \in \Psi(\mathcal{B})$, see Equation (1.3) in the proof of Theorem 1.11. The theorem applies because conditions (Comp1), (Ex), and (Seq) (see Definitions 0.1(iv) and 1.9) hold by Propositions 4.2, 5.2, and 6.18 below.

Secondly, suppose $(\perp \Psi(\mathcal{B}), \Psi(\mathcal{B}))$ is complete. Then $\mathcal{W} \supseteq \mathcal{E}$ is proved similarly using the second part of the first formula of Theorem 0.2 and Equation (1.2). $\square$

4. Condition (Ex)

Section 4 continues to use Setup 3.1. The aim is to prove Proposition 4.2, by which condition (Ex) of Definition 1.9 holds. This is used in the proof of Theorem 3.2. We also establish some other properties of the class $\mathcal{E}$.

Lemma 4.1. If $i \geq 0$ and $q \in Q$ then

(i) $L_i C_q(-) = \text{Tor}^1_i(D \langle q \rangle, -, k)$,

(ii) $R^i K_q(-) = \text{Ext}^i Q(S \langle q \rangle, -)$,

and there are isomorphisms in $R\text{Mod}$,

(iii) $L_i C_q(M \otimes_k B) \cong \text{Tor}^1_i(D \langle q \rangle, M \otimes_k B)$,

(iv) $R^i K_q(M \otimes_k B) \cong \text{Ext}^i Q(S \langle q \rangle, M \otimes_k B)$,

natural in $M \in Q\text{Mod}$ and $B \in R\text{Mod}$.

Proof. Parts (i) and (ii) follow from Equation (3.1) and Paragraph A.5. Parts (iii) and (iv) follow from parts (i) and (ii) combined with Paragraph A.5, parts (iii) and (ii). $\square$

Proposition 4.2. In the situation of Setup 3.1, condition (Ex) of Definition 1.9 holds, that is $\mathcal{E}_L = \mathcal{E}_R$. We write $\mathcal{E} = \mathcal{E}_L = \mathcal{E}_R$ and have

$\mathcal{E} = \{ X \in \mathcal{X} | X \text{ is projective when viewed as an object of } Q\text{Mod} \}$

$= \{ X \in \mathcal{X} | X \text{ is flat when viewed as an object of } Q\text{Mod} \}$

$= \{ X \in \mathcal{X} | X \text{ is injective when viewed as an object of } Q\text{Mod} \}$

Proof. Combining Definition 1.5 and Lemma 4.1(i) shows

$\mathcal{E}_L = \{ X \in \mathcal{X} | \text{If } q \in Q \text{ then } \text{Tor}^1_i(D \langle q \rangle, X) = 0 \}$.

Combining this with Equation (A.3) proves

$\mathcal{E}_L = \{ X \in \mathcal{X} | X \text{ is flat when viewed as an object of } Q\text{Mod} \}$.

Similarly, combining Definition 1.5, Lemma 4.1(ii), and Equation (A.2) proves

$\mathcal{E}_R = \{ X \in \mathcal{X} | X \text{ is injective when viewed as an object of } Q\text{Mod} \}$.

The proposition now follows from Equation (A.4). $\square$

Lemma 4.3. If $M \in Q\text{Mod}$ has finite length and $I \in R\text{Mod}$ is injective, then $M \otimes I \in \mathcal{E}^\perp$.
Proof. Let \( E \in \mathcal{E} \) have the projective resolution \( P \in \mathcal{X} = Q,R\text{Mod} \). Then

\[
\text{Ext}^1_{Q,R} (E, \text{Hom}_k(DS(q), I)) \cong H^1 \text{Hom}_{Q,R} (P, \text{Hom}_k(DS(q), I))
\]

\[
\cong H^1 \text{Hom}_R(DS(q) \otimes P, I)
\]

\[
\cong \text{Hom}_R \left( H_1(DS(q) \otimes P), I \right)
\]

\[
\cong \text{Hom}_R \left( \text{Tor}_1^Q(DS(q), E), I \right)
\]

\[
\cong \text{Hom}_R (0, I)
\]

\[
= 0.
\]

Here (a) is by Paragraph [A.2(ii)] and (b) is because \( I \) is injective. The isomorphism (c) is because \( P \) consists of projective objects in \( \mathcal{X} \), which are also projective when viewed as objects of \( Q\text{Mod} \) by Paragraph [A.4(iv)]. Finally, (d) is by Proposition [1.2].

Hence \( \text{Hom}_k(DS(q), I) \in \mathcal{E}^\perp \), and Paragraph [A.2(vi)] gives \( S(q) \otimes I \in \mathcal{E}^\perp \). However, by Paragraph [A.4(i)] the object \( M \) has a finite filtration with quotients of the form \( S(q) \) for \( q \in Q \), so by Paragraph [A.4(iv)] the object \( M \otimes I \) has a finite filtration with quotients of the form \( S(q) \otimes I \) for \( q \in Q \), and it follows that \( M \otimes I \in \mathcal{E}^\perp \) as claimed.

\[ \square \]

Lemma 4.4. We have \( \mathcal{E}^\perp = \mathcal{E}^{\perp \infty} \) as subcategories of \( \mathcal{X} \) where \( \mathcal{E}^{\perp \infty} = \{ X \in \mathcal{X} \mid \text{Ext}^1_{\mathcal{X}}(\mathcal{E}, X) = 0 \} \).

Proof. The proof of [12, cor. 5.25] goes through for \( \mathcal{X} = Q,R\text{Mod} \), so it is enough to see that \( \mathcal{E} \) is closed under syzygies. Let \( 0 \to \Omega E \to P \to E \to 0 \) be a short exact sequence in \( \mathcal{X} \) with \( P \) projective and \( E \in \mathcal{E} \). Then \( P \) and \( E \) are projective when viewed in \( Q\text{Mod} \), see Proposition [4.2] and Paragraph [A.4(iv)]. Hence \( \Omega E \) is projective when viewed in \( Q\text{Mod} \), so \( \Omega E \in \mathcal{E} \) by Proposition [4.2].

5. Condition (Comp1)

Section 5 continues to use Setup 3.1. The aim is to prove Proposition [5.2] by which condition (Comp1) of Definition [0.1(iv)] holds. This is used in the proof of Theorem [3.2].

Lemma 5.1. If \( q \in Q \) and \( A \in \mathcal{A} \), then \( S_q(A) \in ^1\Psi(\mathcal{B}) \).

Proof. The categories \( \mathcal{M} \) and \( \mathcal{X} \) have enough projective and injective objects by Paragraph [A.3] and the functor \( S_q(-) = S(q) \otimes - \) is exact by Paragraph [A.1(iv)]. Given \( Y \in \Psi(\mathcal{B}) \) we have \( R^1 K_q(Y) = 0 \) by definition of \( \Psi(\mathcal{B}) \), so Lemma [1.3] gives an isomorphism \( Ext^1_{\mathcal{M}}(A, K_q Y) \cong Ext^1_{\mathcal{X}}(S_q A, Y) \). The first \( Ext \) is zero since \( K_q(Y) \in \mathcal{B} \) by definition of \( \Psi(\mathcal{B}) \), so the lemma follows.

\[ \square \]

Proposition 5.2. In the situation of Setup 3.1, condition (Comp1) of Definition [0.1] holds.

Proof. If \( X \in \Phi(\mathcal{A}) \) is given, then \( X \in \mathcal{E}_L = \mathcal{E} \) by definition of \( \Phi(\mathcal{A}) \), so Proposition 1.2 says that \( X \) is flat when viewed as an object of \( Q\text{Mod} \). This means that \(- \otimes X \) is exact, so the filtration (A.6) induces a filtration in \( \mathcal{X} = Q,R\text{Mod} \):

\[
0 = \text{rad}^N_Q X \subseteq \cdots \subseteq \text{rad}^1_Q X \subseteq \text{rad}^0_Q X = X.
\]

Hence \( \mathcal{X} \) is a subcategory of \( \mathcal{X} \) and Proposition 5.2 holds.

\[ \square \]
The final equality is by Equation (A.1). The quotients are
\[
(\text{rad}_Q^i / \text{rad}_Q^{i-1}) \otimes X \overset{(a)}{=} \left( \prod_{p,q \in Q} (DS(p) \otimes S(q))^{n_i(p,q)} \right) \otimes X
\]
\[
\overset{(b)}{=} \prod_{p,q \in Q} (S(q) \otimes (DS(p) \otimes X))^{n_i(p,q)}
\]
\[
= \prod_{p,q \in Q} S_q C_p(X)^{n_i(p,q)}
\]
\[
= (\star),
\]
where (a) is by Equation (A.7), while (b) uses that $- \otimes X$ preserves coproducts, followed by Paragraph A.2(iv). However, $C_p(X) \in \mathcal{A}$ by definition of $\Phi(\mathcal{A})$, so Lemma 5.1 implies $(\star) \in \perp \Psi(\mathcal{B})$, whence also $X \in \perp \Psi(\mathcal{B})$ as desired. □

6. Condition (Seq)

Section 6 continues to use Setup 3.1. The aim is to prove Proposition 6.18 by which condition (Seq) of Definition 1.9 holds. This is used in the proof of Theorem 3.2.

Setup 6.1. In addition to Setup 3.1 Section 6 uses the following setup.

- $M_0 \in \mathcal{Q}_{\text{Mod}}$ is an object of finite length. By Paragraph A.4(ii) it has an augmented minimal projective resolution, which we break into short exact sequences as follows.

\[
\cdots \rightarrow P_2 \xrightarrow{\partial_2^P} P_1 \xrightarrow{\partial_1^P} P_0 \xrightarrow{\pi_0} M_0
\]

Each $P_i$ and each $M_i$ has finite length, and for each $q \in Q$, the functors $DS(q) \otimes -$ and $\text{Hom}_Q(S(q), -)$ vanish on the $\partial_i^P$.

- $B^0 \in \mathcal{R}_{\text{Mod}}$ is a module with an augmented injective resolution, which we break into short exact sequences as follows.

\[
B^0 \xrightarrow{\alpha^0} I^0 \xrightarrow{\beta^0} I^1 \xrightarrow{\alpha^1} B^1 \xrightarrow{\beta^1} I^2 \xrightarrow{\alpha^2} B^2 \xrightarrow{\beta^2} \cdots
\]

Construction 6.2. This construction consists of two parts labelled (i) and (ii).

(i) For each $i \geq 0$ we define a short exact sequence
\[
0 \rightarrow E^i \xrightarrow{\varepsilon^i} T^i \xrightarrow{\tau^i} M_i \otimes B^i \rightarrow 0 \tag{6.1}
\]
in $\mathcal{A}$ as follows:

If $i = 0$ then (6.1) is defined to be
\[
0 \rightarrow 0 \rightarrow M_0 \otimes B_0 \xrightarrow{\text{id}} M_0 \otimes B_0 \rightarrow 0.
\]
If \((6.1)\) has already been defined for a given value \(i \geq 0\), then we use it as the last non-trivial column of the following diagram. The lower right square is a pullback, and the rows and columns are exact, see Paragraph [A.1](iv).

\[ \begin{array}{ccc}
0 & \rightarrow & M_{i+1} \otimes B_i^i \\
\downarrow & & \downarrow \\
E^i & \rightarrow & E^i \\
\downarrow \zeta^i & & \downarrow \varepsilon^i \\
0 & \rightarrow & M_{i+1} \otimes B_i^i \\
\end{array} \]

\[ \begin{array}{ccc}
0 & \rightarrow & M_{i+1} \otimes B_i^i \\
\downarrow \theta^i+1 & & \downarrow \kappa^i+1 \\
E^{i+1} & \rightarrow & T^i \\
\downarrow \eta^i & & \downarrow \tau^i \\
0 & \rightarrow & 0 \\
\end{array} \]

The row which contains \(E^{i+1}\) is used as the first non-trivial row of the following diagram. The upper left square is a pushout, and the rows and columns are exact.

\[ \begin{array}{ccc}
0 & \rightarrow & M_{i+1} \otimes B_i^i \\
\downarrow M_{i+1} \otimes \beta^i & & \downarrow \varepsilon^i+1 \\
\downarrow M_{i+1} \otimes \alpha^i & & \downarrow \tau^i+1 \\
0 & \rightarrow & 0 \\
\end{array} \]

The column which contains \(E^{i+1}\) defines \((6.1)\) for \(i+1\). Note that Diagrams \((6.2)\) and \((6.3)\) define a number of morphisms in addition to those in \((6.1)\). The first steps of the construction give

\[ E^0 = 0 \quad E^1 \cong P_0 \otimes B^0 \quad T^0 \cong M_0 \otimes B^0. \] (6.4)

(ii) Part (i) permits us to construct a short exact sequence of inverse systems as follows: Set

\[ \Delta^i = \begin{cases} 
\text{id}_{T^0} & \text{for } i = 0, \\
\delta^1 \circ \cdots \circ \delta^i & \text{for } i \geq 1
\end{cases} \]

and

\[ W^i = \text{Ker } \Delta^i. \]
Each $\Delta^i$ is an epimorphism because each $\delta^i$ is an epimorphism by Diagram (6.3). Hence there is a short exact sequence of inverse systems, where it is easy to check that the induced morphisms $\omega^i$ are also epimorphisms:

\[
\begin{align*}
\cdots & \xrightarrow{w^2} W^2 \xrightarrow{w^1} W^1 \xrightarrow{w^0} W^0 \\
\cdots & \xrightarrow{\Delta^2} T^2 \xrightarrow{\Delta^1} T^1 \xrightarrow{\Delta^0} T^0
\end{align*}
\]  (6.5)

The inverse limits of the two first systems will be denoted

\[ W = \limleft W^i, \quad T = \limleft T^i. \]  (6.6)

The inverse limit of the third system is

\[ \limleft T^0 \cong \limleft M_0 \otimes_k B^0 \cong M_0 \otimes_k B^0 \]  (6.7)

by Equation (6.4).

**Remark 6.3.** If $q \in Q$ and $B \in \mathcal{B}$ are given, then we can set $M_0 = S(q)$ and $B^0 = B$ in Setup 6.1. We will prove that if $(\mathcal{A}, \mathcal{B})$ is hereditary, then the inverse limit of (6.5) is a short exact sequence

\[ 0 \to W \to T \to S_q(B) \to 0, \]  (6.8)

which can be used as the sequence in condition (Seq)(ii) of Definition 1.9. This will be accomplished in Proposition 6.18.

As an example, suppose that $Q$ is the quiver with relations (0.1), viewed as a $k$-preadditive category. Then $\mathcal{A}$ is the category of chain complexes over $\mathcal{R}$Mod. If $q = 1$ and we write $P_i = I_{-j}$, then

\[ T^i = \cdots \to 0 \to B \to I_0 \to I_{-1} \to \cdots \to I_{-i+1} \to 0 \to \cdots \]

with $B$ in degree 1, and

\[ W^i = \cdots \to 0 \to I_0 \to I_{-1} \to \cdots \to I_{-i+1} \to 0 \to \cdots. \]

The inverse limits become the augmented injective resolution

\[ T = \cdots \to 0 \to B \to I_0 \to I_{-1} \to I_{-2} \to \cdots \]

with $B$ in degree 1, and the injective resolution

\[ W = \cdots \to 0 \to I_0 \to I_{-1} \to I_{-2} \to \cdots. \]

With these $T$ and $W$, the short exact sequence (6.8) is dual to a sequence with projective objects, which was used indirectly by Gillespie in his proof of compatibility, see the proof of [I1, thm. 3.12].

**Lemma 6.4.** If $i \geq 0$ then $E^i \in \mathcal{E}$. 

**Proof.** It follows from Definition 1.5 that $\mathcal{E}$ contains $E^0 = 0$ and is closed under extensions. Diagram (6.2) contains the short exact sequence $0 \to E^i \to E^{i+1} \to P_i \otimes_k B^i \to 0$, so it is enough to show $P_i \otimes_k B^i \in \mathcal{E}$ for each $i \geq 0$. However, for $q \in Q$ we have $L_1C_q(P_i \otimes_k B^i) \cong \text{Tor}_1^Q(DS(q), P_i) \otimes_k B^i = (*)$ by Lemma 4.1(iii). Since $P_i$ is projective, this is $(*) = 0 \otimes_k B^i = 0$. This shows $P_i \otimes_k B^i \in \mathcal{E}_L = \mathcal{E}$. □

**Lemma 6.5.** If $i \geq 0$ and $q \in Q$ then there is a short exact sequence

\[ 0 \to K_q(M_{i+1} \otimes_k B^i) \xrightarrow{K_q(M_{i+1} \otimes \beta^i)} K_q(M_{i+1} \otimes_k I^i) \xrightarrow{K_q(M_{i+1} \otimes \alpha^i)} K_q(M_{i+1} \otimes_k B^{i+1}) \to 0. \]
Lemma 6.7. If Setup 6.1 implies Proof. Since $\Hom_{\mathcal{C}}(\mathcal{C})$ is exact, applying it to the short exact sequence $0 \to B^i \xrightarrow{\delta^i} I^i \xrightarrow{\alpha^i} B^{i+1} \to 0$ gives the sequence in the lemma by Lemma 4.1(iv).

Lemma 6.6. If $i \geq 0$ and $q \in Q$ then:

(i) There is a short exact sequence

$$0 \to K_q(E^i) \xrightarrow{K_q(\varepsilon^i)} K_q(T^i) \xrightarrow{K_q(\tau^i)} K_q(M_i \otimes B^i) \to 0.$$  

(ii) There is an isomorphism

$$R^1 K_q(T^i) \xrightarrow{R^1 K_q(\tau^i)} R^1 K_q(M_i \otimes B^i).$$

Proof. The functor $K_q(-) = \Hom_Q(S\langle q \rangle, -)$ is left exact, so applying it to the short exact sequence (6.1) gives a long exact sequence

$$0 \to K_q(E^i) \xrightarrow{K_q(\varepsilon^i)} K_q(T^i) \xrightarrow{K_q(\tau^i)} K_q(M_i \otimes B^i)$$

$$\to R^1 K_q(E^i) \xrightarrow{R^1 K_q(\varepsilon^i)} R^1 K_q(T^i) \xrightarrow{R^1 K_q(\tau^i)} R^1 K_q(M_i \otimes B^i) \to R^2 K_q(E^i) \to \cdots.$$  

This implies both parts of the lemma because $R^{\geq 1} K_q(E^i) = 0$ by Proposition 4.2 and Lemma 6.4.

Lemma 6.7. If $i \geq 1$ and $q \in Q$ then there is an exact sequence

$$K_q(E^{i+1}) \xrightarrow{K_q(\kappa^{i+1})} K_q(T^i) \xrightarrow{K_q(\tau^i)} K_q(M_i \otimes B^i).$$

Proof. Since $\Hom_Q(S\langle q \rangle, -)$ is left-exact and $\mu_i$ a monomorphism, $\Hom_Q(S\langle q \rangle, \mu_i)$ is injective. But Setup 6.1 implies

$$0 = \Hom_Q(S\langle q \rangle, \partial_i^P) = \Hom_Q(S\langle q \rangle, \mu_i) \circ \Hom_Q(S\langle q \rangle, \pi_i),$$

so we conclude $\Hom_Q(S\langle q \rangle, \pi_i) = 0$. By Lemma 4.1(iv) this implies

$$K_q(\pi_i \otimes B^i) = \Hom_Q(S\langle q \rangle, \pi_i) \otimes B^i = 0.  \tag{6.9}$$

Now observe that the left exact functor $K_q$ preserves the pullback in Diagram (6.2), so there is the following pullback square.

$$\begin{array}{ccc} 
K_q(E^{i+1}) & \xrightarrow{K_q(\kappa^{i+1})} & K_q(T^i) \\
\downarrow K_q(\varphi) & & \downarrow K_q(\tau^i) \\
K_q(P_i \otimes B^i) & \xrightarrow{K_q(\pi_i \otimes B^i)} & K_q(M_i \otimes B^i) 
\end{array}$$

Combining with Equation (6.9) proves the lemma.

Lemma 6.8. If $i \geq 1$ and $q \in Q$ then $\text{Im} K_q(\kappa^i) = \text{Im} K_q(\delta^i)$.  \hfill \square
Proof. If \( i \geq 0 \), then \( K_q \) can be applied to Diagram (6.3). Replacing the third non-trivial column by the images of the relevant morphisms gives the following commutative diagram.

\[
\begin{array}{ccccccc}
0 & \longrightarrow & K_q(M_{i+1} \otimes B^i) & \overset{K_q(\delta^{i+1})}{\longrightarrow} & K_q(E^{i+1}) & \longrightarrow & \text{Im } K_q(\kappa^{i+1}) & \longrightarrow & 0 \\
0 & \longrightarrow & K_q(M_{i+1} \otimes I^i) & \overset{K_q(\tau^{i+1})}{\longrightarrow} & K_q(T^{i+1}) & \longrightarrow & \text{Im } K_q(\delta^{i+1}) & \longrightarrow & 0 \\
0 & \longrightarrow & K_q(M_{i+1} \otimes B^{i+1}) & \longrightarrow & K_q(M_{i+1} \otimes B^{i+1}) & \longrightarrow & 0 & \longrightarrow & 0 \\
0 & \longrightarrow & 0 & \longrightarrow & 0 & \longrightarrow & 0 & \longrightarrow & 0
\end{array}
\]

It is enough to show that the third non-trivial column is a short exact sequence. We use the Nine Lemma, so have to show that the rows and the first two non-trivial columns are short exact. The row which contains an identity morphism is trivially short exact. Since \( K_q \) is left-exact, the other rows are short exact by construction. The first non-trivial column is short exact by Lemma 6.5 and the second by Lemma 6.6(i).

\[ \square \]

Lemma 6.9. If \( i \geq 1 \) and \( q \in Q \) then \( \text{Im } K_q(\varepsilon^i) = \text{Im } K_q(\delta^{i+1}) \).

Proof. Using Lemmas 6.6(i), 6.7, and 6.8 gives the equalities

\[ \text{Im } K_q(\varepsilon^i) = \text{Ker } K_q(\tau^i) = \text{Im } K_q(\kappa^{i+1}) = \text{Im } K_q(\delta^{i+1}) \].

\[ \square \]

Lemma 6.10. If \( i \geq 1 \) and \( q \in Q \) then there are short exact sequences:

\[ (i) \quad 0 \rightarrow \text{Im } K_q(\delta^{i+1}) \overset{\psi'}{\longrightarrow} K_q(T^i) \overset{K_q(\tau^i)}{\longrightarrow} K_q(M_i \otimes B^i) \rightarrow 0, \]

\[ (ii) \quad 0 \rightarrow K_q(M_{i+1} \otimes I^i) \overset{K_q(\gamma^{i+1})}{\longrightarrow} K_q(T^{i+1}) \overset{\psi''}{\longrightarrow} \text{Im } K_q(\delta^{i+1}) \rightarrow 0, \]

where \( \psi' \) is the canonical inclusion and \( \psi'' \) is induced by \( K_q(\delta^{i+1}) \).

Proof. Applying the left exact functor \( K_q \) to the short exact sequence (6.1) gives a long exact sequence containing

\[ K_q(E^i) \overset{K_q(\varepsilon^i)}{\longrightarrow} K_q(T^i) \overset{K_q(\tau^i)}{\longrightarrow} K_q(M_i \otimes B^i) \rightarrow R^1 K_q(E^i). \]

The last term is zero by Proposition 4.2 and Lemma 6.4 and \( \text{Im } K_q(\varepsilon^i) = \text{Im } K_q(\delta^{i+1}) \) by Lemma 6.9 so we get the sequence (i).

Diagram (6.3) contains the short exact sequence \( 0 \rightarrow M_{i+1} \otimes I^i \overset{\gamma^{i+1}}{\longrightarrow} T^{i+1} \overset{\delta^{i+1}}{\longrightarrow} T^i \rightarrow 0 \). Applying the left exact functor \( K_q \) gives the sequence (ii).

\[ \square \]
**Definition 6.11.** If \( i \geq 0 \) and \( q \in Q \), then \( \varphi^{i+2} \) is the unique morphism which makes the following square commutative, where the vertical morphisms are the canonical inclusions.

\[
\begin{array}{ccc}
\text{Im } K_q(\delta^{i+2}) & \xrightarrow{\varphi^{i+2}} & \text{Im } K_q(\delta^{i+1}) \\
\downarrow & & \downarrow \\
K_q(T^{i+1}) & \xrightarrow{K_q(\delta^{i+1})} & K_q(T^i)
\end{array}
\]

**Lemma 6.12.** If \( i \geq 1 \) and \( q \in Q \) then there is a short exact sequence

\[
0 \to K_q(M_{i+1}) \xrightarrow{k_i} B^i \to \text{Im } K_q(\delta^{i+2}) \xrightarrow{\varphi^{i+2}} \text{Im } K_q(\delta^{i+1}) \to 0.
\]

**Proof.** In view of Lemma 6.11(iv), it is enough to show that there is a commutative diagram as follows, in which the first non-trivial row is a short exact sequence.

To construct the diagram, observe that it has three non-trivial columns, each of which is short exact. The first comes from Lemma 6.5, the second from Lemma 6.10(i), and the third is trivial. As for the morphisms between the columns, \( K_q(\gamma^{i+1}) \) is obtained from Diagram (6.3), which also shows that the lower left square is commutative. There is a unique induced morphism \( \psi'' \) making the upper left square commutative. The morphism \( \psi'' \) is induced by \( K_q(\delta^{i+1}) \), and the upper right square is commutative by Definition 6.11. The lower right square is trivially commutative.

We use the Nine Lemma, so it remains to show that the last two non-trivial rows are short exact. The row which contains an identity morphism is trivially short exact, and the row above it is short exact by Lemma 6.10(ii).

**Lemma 6.13.** If \( i \geq 1 \) and \( q \in Q \) then \( R^1K_q(\delta^i) = 0 \).

**Proof.** If \( i \geq 0 \) then Diagram (6.3) contains a short exact sequence \( 0 \to M_{i+1} \xrightarrow{\gamma^{i+1}} T^{i+1} \xrightarrow{\delta^{i+1}} T^i \to 0 \). It induces a long exact sequence containing

\[
R^1K_q(M_{i+1} \xrightarrow{k_i} I^i) \xrightarrow{R^1K_q(\gamma^{i+1})} R^1K_q(T^{i+1}) \xrightarrow{R^1K_q(\delta^{i+1})} R^1K_q(T^i),
\]

so it is enough to see that \( R^1K_q(\gamma^{i+1}) \) is an epimorphism.
Setup (6.1) gives an epimorphism $I^i \xrightarrow{\alpha^i} B^{i+1}$, and
\[ R^1 K_q(M_{i+1} \otimes_k I^i) \xrightarrow{R^1 K_q(M_{i+1} \otimes \alpha^i)} R^1 K_q(M_{i+1} \otimes_k B^{i+1}) \]
is an epimorphism because Lemma (6.1)(iv) says it can be identified with the morphism obtained by applying the exact functor $\text{Ext}_Q^1(S(q), M_{i+1}) \otimes -$ to $\alpha^i$. Combining this with Lemma (6.6)(ii) shows that applying $R^1 K_q$ to the lower square in Diagram (6.3) gives the following commutative square with an epimorphism on the left and an isomorphism on the right.

\[
\begin{array}{ccc}
R^1 K_q(M_{i+1} \otimes I^i) & \xrightarrow{R^1 K_q(\gamma^{i+1})} & R^1 K_q(T^{i+1}) \\
\downarrow & & \downarrow \\
R^1 K_q(M_{i+1} \otimes \alpha^i) & \xrightarrow{R^1 K_q(\sigma^{i+1})} & R^1 K_q(M_{i+1} \otimes B^{i+1})
\end{array}
\]

Hence $R^1 K_q(\gamma^{i+1})$ is an epimorphism as desired. \(\square\)

**Lemma 6.14.** For each $q \in Q$ we have:

(i) $K_q(T) \cong \varprojlim K_q(T^i)$,

(ii) There is a short exact sequence

\[ 0 \to R^1 \varprojlim K_q(T^i) \to R^1 K_q(T) \to \varprojlim R^1 K_q(T^i) \to 0. \]

**Proof.** Recall from Construction (6.2)(ii) that $T$ is the inverse limit of $\cdots \xrightarrow{\delta^2} T^1 \xrightarrow{\delta^1} T^0$. Each $\delta^i$ is an epimorphism by Diagram (6.3), so this system satisfies the Mittag-Leffler condition and there is a short exact sequence

\[ 0 \to T \to \prod_i T^i \xrightarrow{\text{id} - \text{shift}} \prod_i T^i \to 0, \]

see Paragraph (A.7). It gives a long exact sequence containing

\[ 0 \to K_q(T) \to K_q \left( \prod_i T^i \right) \xrightarrow{K_q(\text{id} - \text{shift})} K_q \left( \prod_i T^i \right) \]

\[ \to R^1 K_q(T) \to R^1 K_q \left( \prod_i T^i \right) \xrightarrow{R^1 K_q(\text{id} - \text{shift})} R^1 K_q \left( \prod_i T^i \right). \quad (6.10) \]

Combining Equation (3.1) and Paragraph (A.5)(i) shows that there are natural isomorphisms

\[ R^i K_q \left( \prod_i T^i \right) \xrightarrow{\cong} \prod_i R^i K_q(T^i), \]

so (6.10) can be identified with

\[ 0 \to K_q(T) \to \prod_i K_q(T^i) \xrightarrow{\text{id} - \text{shift}} \prod_i K_q(T^i) \]

\[ \to R^1 K_q(T) \to \prod_i R^1 K_q(T^i) \xrightarrow{\text{id} - \text{shift}} \prod_i R^1 K_q(T^i), \]

which implies both parts of the lemma. \(\square\)

**Lemma 6.15.** Assume that $(\mathcal{A}, \mathcal{B})$ is hereditary, that $B^0 \in \mathcal{B}$, and that $M \in Q\text{-Mod}$ has finite length. If $i \geq 0$ and $q \in Q$ then $K_q(M) \otimes_k B^i \in \mathcal{B}$. 
Proof. Since \((\mathcal{A}, \mathcal{B})\) is hereditary, \(B^i \in \mathcal{B}\) for each \(i \geq 0\) by \([12]\) lem. 5.24]. Since \(M \in \mathcal{Q}\text{Mod}\) has finite length, \(\dim_k K_q(M) < \infty\) by Paragraph \(\mathcal{A.4}\)vi. Hence \(K_q(M) \otimes B^i\) is in \(\mathcal{B}\) because it is a finite coproduct of copies of \(B^i\).

Lemma 6.16. Assume that \((\mathcal{A}, \mathcal{B})\) is hereditary and that \(B^0 \in \mathcal{B}\). Then
\[
\lim \left(\cdots \rightarrow \text{Im} K_q(\delta^3) \overset{\varphi^3}{\rightarrow} \text{Im} K_q(\delta^2) \overset{\varphi^2}{\rightarrow} \text{Im} K_q(\delta^1) \right)
\]
is in \(\mathcal{B}\).

Proof. Since \(\mathcal{B} = \mathcal{A}^\perp\), the Lukas Lemma implies that it is enough to show the following, see Paragraph \(\mathcal{A.7}\)

1. \(\varphi^i\) is an epimorphism for \(i \geq 3\).
2. \(\text{Im} K_q(\delta^2) \in \mathcal{B}\).
3. \(\text{Ker} \varphi^i \in \mathcal{B}\) for \(i \geq 3\).

Lemma 6.12 gives (i). It also gives \(\text{Ker} \varphi^i \cong K_q(M_{i+1}) \otimes_k B^i\) for \(i \geq 1\), and this is in \(\mathcal{B}\) by Lemma 6.15 since \(M_{i+1}\) has finite length by Setup 6.1. This shows (iii).

To show (ii), we compute:
\[
\text{Im} K_q(\delta^2) \overset{(a)}{=} \text{Im} K_q(e^1) \overset{(b)}{=} K_q(E^1) \overset{(c)}{=} K_q(P_0 \otimes_k B^0) \overset{(d)}{=} K_q(P_0) \otimes_k B^0.
\]
Here (a) is by Lemma 6.9. For (b), apply the left exact functor \(K_q\) to the short exact sequence (6.1) for \(i = 1\). Equation (6.4) implies (c), and Lemma 4.1(iv) implies (d). But \(K_q(P_0) \otimes_k B^0 \in \mathcal{B}\) by Lemma 6.15 since \(P_0\) has finite length by Setup 6.1.

Lemma 6.17. Assume that \((\mathcal{A}, \mathcal{B})\) is hereditary and that \(B^0 \in \mathcal{B}\). Then \(T \in \Psi(\mathcal{B})\).

Proof. Let \(q \in Q\) be given. By Definition 6.15 we must show \(K_q(T) \in \mathcal{B}\) and \(R^1K_q(T) = 0\).

\(K_q(T) \in \mathcal{B}\): Lemma 6.10(i) gives the vertical short exact sequences in the following diagram.

\[
\begin{array}{c}
\cdots \rightarrow \text{Im} K_q(\delta^4) \overset{\varphi^4}{\rightarrow} \text{Im} K_q(\delta^3) \overset{\varphi^3}{\rightarrow} \text{Im} K_q(\delta^2) \\
\cdots \rightarrow K_q(T^3) \overset{K_q(\delta^3)}{\rightarrow} K_q(T^2) \overset{K_q(\delta^2)}{\rightarrow} K_q(T^1) \\
\cdots \rightarrow K_q(M_3 \otimes_k B^3) \overset{0}{\rightarrow} K_q(M_2 \otimes_k B^2) \overset{0}{\rightarrow} K_q(M_1 \otimes_k B^1)
\end{array}
\]

The upper squares are commutative by Definition 6.11 and the lower squares are obviously commutative, so the diagram constitutes a short exact sequence of inverse systems. The long exact \(\lim\) sequence contains
\[
0 \rightarrow \lim \text{Im} K_q(\delta^i) \rightarrow \lim \text{Im} K_q(T^i) \rightarrow \lim \text{Im} K_q(M_i \otimes_k B^i),
\]
where the last term is zero because all morphisms in the third inverse system are zero. This gives the first of the following isomorphisms,
\[
\lim \text{Im} K_q(\delta^i) \cong \lim \text{Im} K_q(T^i) \cong K_q(T),
\]
and the second isomorphism is by Lemma 6.14(i). However, the left hand side is in \( \mathcal{B} \) by Lemma 6.16.

\[ R^1K_q(T) = 0: \] We show this without using the assumption \( B^0 \in \mathcal{B} \). If \( i \geq 2 \) and \( q \in Q \) then the epimorphism in the short exact sequence of Lemma 6.12 shows

\[ \text{Im} \left( K_q(\delta^i) \circ K_q(\delta^{i+1}) \right) = \text{Im} \, K_q(\delta^i). \]

Hence the system

\[ \cdots \to K_q(T^1) \xrightarrow{K_q(\delta^1)} K_q(T^0) \]

satisfies the Mittag-Leffler condition, so the first term of the exact sequence in Lemma 6.14(ii) is zero, see Paragraph A.7. The last term is zero because Lemma 6.13 says that the morphisms vanish in the inverse system

\[ \cdots \to R^1K_q(T^1) \xrightarrow{R^1K_q(\delta^1)} R^1K_q(T^0). \]

Hence \( R^1K_q(T) = 0 \) as desired. \( \square \)

**Proposition 6.18.** In the situation of Setup 3.1, if \((\mathcal{A}, \mathcal{B})\) is hereditary then condition (Seq) of Definition 7.9 holds.

**Proof.** We show condition (Seq)(ii). Condition (Seq)(i) follows by a dual argument, parts of which are simplified by exactness of direct limits.

Let \( q \in Q \) and \( B \in \mathcal{B} \) be given. Set \( M_0 = S(q) \) and \( B^0 = B \) in Setup 6.1. Consider the short exact sequence of inverse systems (6.5). The morphisms in the inverse systems are epimorphisms, so Paragraph A.7 says there is an induced short exact sequence

\[ 0 \to \varprojlim W \to \varprojlim T \to \varprojlim S \to 0, \]

which by Equations (6.6) and (6.7) reads

\[ 0 \to W \to T \to S \to 0, \]

where we have used \( M_0 \otimes_k B^0 = S(q) \otimes_k B = S(q)(B) \) by Equation (3.1). We claim this sequence can be used as the sequence in condition (Seq)(ii).

We have \( T \in \Psi(\mathcal{B}) \) by Lemma 6.17, so it remains to show \( \text{Ext}^2_{Q,R}(\mathcal{E}, W) = 0 \). By Lemma 4.4 it is enough to show \( W \in \mathcal{E}^{\perp} \). The Lukas Lemma can be applied to the first inverse system in (6.5) because \( \omega^i \) is an epimorphism for \( i \geq 1 \). Hence it is sufficient to show the following, see Paragraph A.7

(i) \( W^0 \in \mathcal{E}^{\perp} \).

(ii) \( \text{Ker} \, \omega^i \in \mathcal{E}^{\perp} \) for \( i \geq 1 \).

But (i) is trivially true because \( W^0 = \text{Ker} \, \Delta^0 = \text{Ker} \, \text{id}_{T^0} = 0 \). For (ii), let \( i \geq 1 \) be given. From Diagram (6.5) it is easy to prove the first of the isomorphisms

\[ \text{Ker} \, \omega^i \cong \text{Ker} \, \delta^i \cong M_i \otimes_k I^{i-1} = (*), \]

and the second isomorphism is by Diagram (6.3). But \( M_i \) has finite length and \( I^{i-1} \) is injective by Setup 6.1 so \( (*) \in \mathcal{E}^{\perp} \) by Lemma 4.3. \( \square \)
Section 7 continues to use Setup 3.1 except that:

- $Q$ is the quiver with relations (0.3), viewed as a $k$-preadditive category; see Section 0.vi.

We think of objects of $Q\text{Mod}$ and $X$ as quiver representations. In particular, the value of $X$ at $q$ is denoted $X_q$, instead of $X(q)$ which would be used if we thought of $X$ as a functor. Recall from Section 0.vi that each $X \in X$ has the form

$$X_N \xrightarrow{\partial^X_N} X_{N-1} \xrightarrow{\partial^X_{N-1}} \cdots X_1 \xrightarrow{\partial^X_1} X_0,$$

where two consecutive morphisms compose to 0. For $0 \leq q \leq N-1$ there is a homology functor $X \xrightarrow{H_q} R\text{Mod}$ defined in an obvious fashion.

**Lemma 7.1.** For $0 \leq q \leq N-1$ and $X \in X$ we have

$$C_q(X) = \text{Coker}(\partial^X_{q+1}) \quad K_q(X) = \text{Ker}(\partial^X_q), \quad R^1 K_q = H_{q-1} \quad L_1 C_q = H_{q+1},$$

with subscripts taken modulo $N$.

**Proof.** The functor $S_q : \mathcal{M} \to \mathcal{X}$ sends an object $M$ to an object $S_q(M)$ which has $M$ at vertex $q$ and 0 at all other vertices. The two first formulae in the lemma are easily verified to define left and right adjoint functors to $S_q$, hence define $C_q$ and $K_q$.

The simple object $S(q)$ has $k$ at vertex $q$ and 0 at every other vertex. There is an indecomposable projective object $P(q)$, see Paragraph A.4(i). It has copies of $k$ at vertices $q$ and $q-1$ and 0 at every other vertex. The homomorphism between the copies of $k$ is the identity map, and vertices are taken modulo $N$. This permits to determine the minimal augmented projective resolution of $S(q)$ in $Q\text{Mod}$. The first terms are the following, with indices taken modulo $N$.

$$\cdots \to P(q-2) \to P(q-1) \to P(q) \to S(q) \to 0 \to \cdots$$

Each morphism of projective objects is induced by an arrow in $Q$. We can now compute $R^1 K_q(X) = \text{Ext}^1_Q(S(q), X)$ by using the projective resolution and Paragraph A.4(iii). This gives the third formula in the lemma, and the fourth formula is proved similarly. □

**Proof of Theorem B** Paragraph 2.4 means that Theorems 3.2 and 3.3 apply to the setup of Theorem B. The formulae for $\Phi(\mathcal{A})$ and $\Psi(\mathcal{B})$ in Theorem 3.2 can be converted into the formulae in Theorem B part (i) by using Lemma 7.1 and Theorem 3.3 implies Theorem B part (ii). □

Section 8 continues to use Setup 3.1 except that:

- $Q$ is the repetitive quiver $\mathbb{Z}A_3$ modulo the mesh relations, viewed as a $k$-preadditive category; see Section 0.vii.

As in Section 7 we think of objects of $Q\text{Mod}$ and $X$ as quiver representations. For $j \in \mathbb{Z}$ there is an arrow $(j,0) \to (j,1)$ in $Q$, so a corresponding homomorphism $X_{(j,0)} \to X_{(j,1)}$ for each $X \in \mathcal{X}$. This and similar homomorphisms are used in the following two lemmas.

**Lemma 8.1.** For $j \in \mathbb{Z}$ and $X \in \mathcal{X}$ we have:
Lemma 8.2. For \( H \) relations imply that the arguments of \( H \) are given by
\[
C_{(j,0)}(X) = \text{Coker}(X_{(j+1,1)} \to X_{(j,0)}),
C_{(j,1)}(X) = \text{Coker}(X_{(j,0)} \oplus X_{(j+1,2)} \to X_{(j,1)}),
C_{(j,2)}(X) = \text{Coker}(X_{(j,1)} \to X_{(j,2)}).
\]

(ii) The functors \( K_q \) are given by
\[
K_{(j,0)}(X) = \text{Ker}(X_{(j,0)} \to X_{(j,1)}),
K_{(j,1)}(X) = \text{Ker}(X_{(j,1)} \to X_{(j-1,0)} \oplus X_{(j,2)}),
K_{(j,2)}(X) = \text{Ker}(X_{(j,2)} \to X_{(j-1,1)}).
\]

Proof. The functor \( S_q : \mathcal{M} \to \mathcal{X} \) sends an object \( M \) to an object \( S_q(M) \) which has \( M \) at vertex \( q \) and \( 0 \) at all the other vertices. The formulae in the lemma are easily verified to define left and right adjoint functors to \( S_q \), hence define \( C_q \) and \( K_q \). \qed

Lemma 8.2. For \( j \in \mathbb{Z} \) and \( X \in \mathcal{X} \) we have:
\[
R^1K_{(j,0)}(X) = \text{H}(X_{(j,0)} \to X_{(j,1)} \to X_{(j-1,0)}),
R^1K_{(j,1)}(X) = \text{H}(X_{(j,1)} \to X_{(j-1,0)} \oplus X_{(j,2)} \to X_{(j-1,1)}),
R^1K_{(j,2)}(X) = \text{H}(X_{(j,2)} \to X_{(j-1,1)} \to X_{(j-1,2)}).
\]

Here \( \text{H} \) denotes the homology of a three term chain complex, taken at the middle term. The mesh relations imply that the arguments of \( \text{H} \) are indeed chain complexes.

Proof. For readability, the simple object \( S((j, \ell)) \) of \( Q\text{Mod} \) is denoted \( S(j, \ell) \). It has \( k \) at vertex \( (j, \ell) \) and \( 0 \) at every other vertex. The indecomposable projective object \( P((j, \ell)) \) of \( Q\text{Mod} \) is denoted \( P(j, \ell) \). It is one of the following, where in each case, one of the vertices is identified by a superscript.
This permits to determine the minimal augmented projective resolutions of the simple objects in $\mathcal{Q}_{\text{Mod}}$. In each case, the first terms are the following.

$$
\cdots \rightarrow P(j-1,0) \rightarrow P(j,1) \rightarrow P(j,0) \rightarrow S(j,0) \rightarrow 0 \rightarrow \cdots
$$

$$
\cdots \rightarrow P(j-1,1) \rightarrow P(j-1,0) \oplus P(j,2) \rightarrow P(j,1) \rightarrow S(j,1) \rightarrow 0 \rightarrow \cdots
$$

$$
\cdots \rightarrow P(j-1,2) \rightarrow P(j-1,1) \rightarrow P(j,2) \rightarrow S(j,2) \rightarrow 0 \rightarrow \cdots
$$

Each morphism of projective objects is induced by arrows in $Q$. We can now compute $R^1K_{(j,\ell)}(X) = \text{Ext}_Q^1(S(j,\ell), X)$ by using the projective resolutions and Paragraph A.4(iii), and this gives the formulae in the lemma.

**Proof of Theorem C** Paragraph 2.4 means that Theorem 3.2 applies to the setup of Theorem C. The formulae for $\Phi(\mathcal{A})$ and $\Psi(\mathcal{B})$ in Theorem 3.2 can be converted into the formulae in Theorem C by combining Definition 1.5, Proposition 4.2, and Lemmas 8.1 and 8.2.

Appendix A. Compendium on functor categories

In this appendix, $k$, $Q$, and $R$ are as in Setup 3.1. $k$ is a field, $R$ a $k$-algebra, $Q$ a small $k$-preadditive category satisfying conditions (Fin), (Rad), and (SelfInj) of Definition 2.3. The homomorphism functor and the radical of $Q$ will be denoted $Q(-,-)$ and $\text{rad}_Q(-,-)$, see [1, sec. A.3], [8, sec. 3.2], and [21, p. 303].

The appendix explains some properties of the functor categories $q_{\text{Mod}}, \text{Mod}_Q, q_{R\text{Mod}},$ and $q_{\text{Mod}_Q}$ from Paragraph 2.2, which are used extensively in Sections 3 through 6. They share many properties of the module categories $\Lambda\text{Mod}, \text{Mod}_Q, \Lambda_R\text{Mod},$ and $\Lambda\text{Mod}_Q$, where $\Lambda$ is a finite dimensional $k$-algebra. This follows from conditions (Fin) and (Rad), which imply that $Q$ is a locally bounded spectroid in the terminology of [8, secs. 3.5 and 8.3]. We can even think of $\Lambda$ as self-injective because condition (SelfInj) implies that projective, injective, and flat objects coincide in each of $q_{\text{Mod}}$ and $q_{\text{Mod}_Q}$, see Paragraph A.6.

Note that each statement in the appendix for $q_{\text{Mod}}$ has an analogue for $q_{\text{Mod}_Q}$.

The appendix has been included because we do not have references for all the results we need on functor categories. Some hold by [8] as we shall point out along the way. The rest follow by amending the proofs in the following references: [2, chp. 1], [3, secs. 1-4], [4, secs. 1 and 2], [19, app. B], [25].

A.1 (Hom and tensor functors). The following functors are used extensively in this paper.

(i) The homomorphism functor of $q_{\text{Mod}}$ is $\text{Hom}_Q(-,-) : (q_{\text{Mod}})^{\circ} \times q_{\text{Mod}} \rightarrow q_{\text{Mod}}$.

It is defined by $\text{Hom}_Q(M,N)$ being the set of $k$-linear natural transformations $M \rightarrow N$ for $M,N \in q_{\text{Mod}}$.

If $X \in q_{R\text{Mod}}$, then $X$ is a $k$-linear functor $Q \rightarrow R\text{Mod}$, so $R$ acts on $\text{Hom}_Q(M,X)$. Hence $\text{Hom}_Q$ can also be viewed as a functor $\text{Hom}_Q(-,-) : (q_{\text{Mod}})^{\circ} \times q_{R\text{Mod}} \rightarrow R\text{Mod}$.

(ii) There are functors

- $\otimes - : q_{\text{Mod}} \times q_{\text{Mod}} \rightarrow q_{\text{Mod}}$,

- $\otimes - : q_{\text{Mod}} \times q_{R\text{Mod}} \rightarrow R\text{Mod}$,

- $\otimes - : q_{\text{Mod}_Q} \times q_{R\text{Mod}} \rightarrow q_{R\text{Mod}}$. 

They are right exact in each variable, and the last of them satisfies
\[ Q(-, -) \otimes X \cong X \quad (A.1) \]
naturally in \( X \in Q,R \text{Mod} \). This makes sense because \( Q(-, -) \) is an object of \( Q \text{Mod}_Q \).

(iii) There is a functor
\[ \text{Hom}_k(-, -) : (\text{Mod}_Q)^{op} \times R \text{Mod} \to Q,R \text{Mod} \]
defined by
\[ \text{Hom}_k(N, B)(q) = \text{Hom}_k(N(q), B), \]
where \( \text{Hom}_k \) on the right hand side is \( \text{Hom} \) of \( k \)-vector spaces. It is exact in both variables.

(iv) There is a functor
\[ - \otimes_k - : Q \text{Mod} \times R \text{Mod} \to Q,R \text{Mod} \]
defined by
\[ (M \otimes_k B)(q) = M(q) \otimes_k B, \]
where \( \otimes_k \) on the right hand side is tensor of \( k \)-vector spaces. It is exact in both variables.

(v) There is a functor
\[ - \otimes_k - : \text{Mod}_Q \times Q \text{Mod} \to Q \text{Mod}_Q \]
defined by
\[ (M \otimes_k N)(q', q'') = M(q') \otimes_k N(q''), \]
where \( \otimes_k \) on the right hand side is tensor of \( k \)-vector spaces. It is exact in both variables.

(vi) We can view \( D(-) = \text{Hom}_k(-, k) \) as a functor \( Q \text{Mod} \to \text{Mod}_Q \).

A.2 (Standard isomorphisms). The functors from Paragraph A.1 permit the following standard isomorphisms, among others.

(i) There is an adjunction isomorphism in \( k \text{Mod} \),
\[ \text{Hom}_{Q,R}(M \otimes_k B, X) \cong \text{Hom}_R(B, \text{Hom}_Q(M, X)), \]
natural in \( M \in Q \text{Mod} \), \( B \in R \text{Mod} \), \( X \in Q,R \text{Mod} \).

(ii) There is an adjunction isomorphism in \( k \text{Mod} \),
\[ \text{Hom}_R(M \otimes X, B) \cong \text{Hom}_{Q,R}(X, \text{Hom}_k(M, B)), \]
natural in \( M \in \text{Mod}_Q \), \( X \in Q,R \text{Mod} \), \( B \in R \text{Mod} \).

(iii) There is an associativity isomorphism in \( R \text{Mod} \),
\[ (M \otimes_k N) \otimes_k B \cong M \otimes_k (N \otimes_k B), \]
natural in \( M \in \text{Mod}_Q \), \( N \in Q \text{Mod} \), \( B \in R \text{Mod} \), where \( \otimes_k \) on the left hand side is tensor of \( k \)-vector spaces.

(iv) There is an associativity isomorphism in \( Q,R \text{Mod} \),
\[ (M \otimes_k N) \otimes_k X \cong N \otimes_k (M \otimes_k X), \]
natural in \( M \in \text{Mod}_Q \), \( N \in Q \text{Mod} \), \( X \in Q,R \text{Mod} \).
(v) There is a morphism in \( \mathcal{R} \text{Mod} \),
\[
\text{Hom}_Q(M, N) \otimes B \to \text{Hom}_Q(M, N \otimes B),
\]
natural in \( M, N \in \mathcal{Q} \text{Mod} \), \( B \in \mathcal{R} \text{Mod} \). It is an isomorphism if \( M \) has finite length. Note that \( \otimes \) on the left hand side is tensor of \( k \)-vector spaces.

(vi) There is a morphism in \( \mathcal{Q}, \mathcal{R} \text{Mod} \),
\[
M \otimes_k B \to \text{Hom}_k(DM, B),
\]
natural in \( M \in \mathcal{Q} \text{Mod} \), \( B \in \mathcal{R} \text{Mod} \). It is an isomorphism if \( M \) has finite length.

A.3 (Products and coproducts). We will explain products and coproducts in \( \mathcal{Q} \text{Mod} \). What we say applies equally to \( \text{Mod}_Q \) and \( \mathcal{Q}, \mathcal{R} \text{Mod} \).

Let \( \{M_\alpha\} \) be a family of objects of \( \mathcal{Q} \text{Mod} \). The product of the \( M_\alpha \) in \( \mathcal{Q} \text{Mod} \) is given by
\[
\left( \prod_\alpha M_\alpha \right)(-)=\prod_\alpha M_\alpha(-),
\]
where the second \( \prod \) is in \( k \text{Mod} \). There is a similar formula for \( \coprod \). This implies that \( \mathcal{Q} \text{Mod} \) inherits the following properties from \( k \text{Mod} \): It is complete and cocomplete, and products, coproducts, and filtered colimits preserve exact sequences.

Each of the tensor product functors from Paragraph A.1 preserves coproducts in each variable.

A.4 (Projective, injective, and simple objects). Each of the categories \( \mathcal{Q} \text{Mod} \), \( \text{Mod}_Q \), \( \mathcal{Q}, \mathcal{R} \text{Mod} \), and \( \mathcal{Q} \text{Mod}_Q \) has enough projective objects and enough injective objects. We list some additional properties.

(i) By \( \text{[S]} \) sec. 3.7] we have the following: For each \( q \in Q \) there is an indecomposable projective object
\[
P\langle q \rangle = Q(q, -)
\]
in \( \mathcal{Q} \text{Mod} \). By conditions (Fin) and (Rad) of Definition 2.3 it has finite length and there is a unique maximal subobject \( rP\langle q \rangle \subset P\langle q \rangle \) given by \( rP\langle q \rangle = \text{rad}_Q(q, -) \). The quotient
\[
S\langle q \rangle = P\langle q \rangle/rP\langle q \rangle
\]
is a simple object in \( \mathcal{Q} \text{Mod} \), which satisfies
\[
S\langle q \rangle(p) \cong \begin{cases} k & \text{for } p = q, \\ 0 & \text{otherwise}. \end{cases}
\]
The simple objects of \( \mathcal{Q} \text{Mod} \) are precisely the \( S\langle q \rangle \) for \( q \in Q \). The simple objects of \( \text{Mod}_Q \) are precisely the duals \( \text{DS}\langle q \rangle \) for \( q \in Q \).

(ii) By \( \text{[S]} \) p. 85, ex. 2] we have the following: Each \( M \in \mathcal{Q} \text{Mod} \) has an augmented projective resolution
\[
\cdots \xrightarrow{\partial_2} P_2 \xrightarrow{\partial_1} P_1 \xrightarrow{\partial_0} P_0 \xrightarrow{\partial_0} M \rightarrow 0 \rightarrow \cdots,
\]
which can be constructed by choosing an epimorphism \( P_0 \xrightarrow{\partial_0} M \) with \( P_0 \) projective, then, when \( \partial_{i-1} \) has been defined, choosing an epimorphism \( P_i \xrightarrow{\partial_i} \text{Ker} \partial_{i-1} \) and defining \( \partial_i \) to be the composition \( P_i \xrightarrow{\partial_i} \text{Ker} \partial_{i-1} \xrightarrow{\partial_{i-1}} P_{i-1} \).

If \( M \) has finite length, then condition (Fin) of Definition 2.3 implies that each \( P_i \) can be chosen as a coproduct of finitely many objects of the form \( P\langle q \rangle \), and then each \( P_i \) and each \( \text{Ker} \partial_i \) has finite length. Moreover, by choosing each of the epimorphisms \( P_0 \xrightarrow{\partial_0} M \) and \( P_i \xrightarrow{\partial_i} \text{Ker} \partial_{i-1} \) as a projective cover, we can even make the resolution minimal, that is, if \( i \geq 1 \) then \( \partial_i \) is in the radical of \( \mathcal{Q} \text{Mod} \). This implies that the functors \( \text{DS}\langle q \rangle \otimes - \) and \( \text{Hom}_Q(S\langle q \rangle, -) \) vanish on \( \partial_i \).
(iii) A morphism $p \xrightarrow{\pi} q$ in $Q$ induces a natural transformation $Q(q, -) \to Q(p, -)$, that is, a morphism $P\langle q \rangle \to P\langle p \rangle$. By Yoneda’s Lemma, this in turn induces a commutative square

$$
\begin{array}{ccc}
\text{Hom}_Q(P\langle p \rangle, X) & \longrightarrow & \text{Hom}_Q(P\langle q \rangle, X) \\
\downarrow & & \downarrow \\
X(p) & \longrightarrow & X(q),
\end{array}
$$

natural in $X \in Q,R\text{Mod}$, where the vertical arrows are isomorphisms.

(iv) If $X$ is a projective object of $Q,R\text{Mod}$, then $X$ is projective when viewed as an object of $Q\text{Mod}$.

(v) $M,N \in Q\text{Mod}$ have finite length $\Rightarrow \dim_k \text{Hom}_Q(M,N) < \infty$.

A.5 (Ext and Tor functors). The functors $\text{Hom}_Q$ and $\otimes$ of Paragraph A.1 have right and left derived functors,

$$
\begin{align*}
\text{Ext}^i_Q(-,-) : (Q\text{Mod})^\circ \times Q\text{Mod} & \to k\text{Mod}, \\
\text{Tor}^i_Q(-,-) : \text{Mod}_Q \times Q\text{Mod} & \to k\text{Mod}
\end{align*}
$$

for $i \geq 0$. Like $\text{Hom}_Q$ and $\otimes$ they can also be viewed as functors

$$
\begin{align*}
\text{Ext}^i_Q(-,-) : (Q\text{Mod})^\circ \times Q,R\text{Mod} & \to R\text{Mod}, \\
\text{Tor}^i_Q(-,-) : \text{Mod}_Q \times Q,R\text{Mod} & \to R\text{Mod}.
\end{align*}
$$

We list some additional properties.

(i) Since products preserve exact sequences, there are isomorphisms in $R\text{Mod}$,

$$
\text{Ext}^i_Q(N, \prod_{\alpha} M_\alpha) \xrightarrow{\cong} \prod_{\alpha} \text{Ext}^i_Q(N, M_\alpha),
$$

natural in $N \in Q\text{Mod}$ and $M_\alpha \in Q,R\text{Mod}$.

(ii) The morphism in Paragraph A.2(v) induces standard morphisms in $R\text{Mod}$,

$$
\text{Ext}^i_Q(M,N) \otimes_k B \to \text{Ext}^i_Q(M,N \otimes_k B),
$$

natural in $M,N \in Q\text{Mod}, B \in R\text{Mod}$. They are isomorphisms if $M$ has finite length.

(iii) The isomorphism in Paragraph A.2(iii) induces standard isomorphisms in $R\text{Mod}$,

$$
\text{Tor}^i_Q(M,N) \otimes_k B \xrightarrow{\cong} \text{Tor}^i_Q(M,N \otimes_k B),
$$

natural in $M \in \text{Mod}_Q, N \in Q\text{Mod}, B \in R\text{Mod}$.

A.6 (Criteria for injectivity and flatness). Condition (Fin) of Definition 2.3 implies that $M \in Q\text{Mod}$ satisfies

$$
M \text{ is injective } \iff \text{ If } q \in Q \text{ then } \text{Ext}^1_Q(S\langle q \rangle, M) = 0. \hspace{1cm} (A.2)
$$

Similarly, $M$ is flat if the functor $- \otimes M$ is exact, and

$$
M \text{ is flat } \iff \text{ If } q \in Q \text{ then } \text{Tor}^1_Q(DS\langle q \rangle, M) = 0. \hspace{1cm} (A.3)
$$

Conditions (Fin) and (SelfInj) of Definition 2.3 imply that $M \in Q\text{Mod}$ satisfies

$$
M \text{ is projective } \iff M \text{ is flat } \iff M \text{ is injective}. \hspace{1cm} (A.4)
$$
A.7 (Inverse limits). We will explain inverse limits in $Q\text{Mod}$. What we say applies equally to $Mod_Q$ and $Q,R\text{Mod}$.

Since products exist and preserve exact sequences, the results on (derived) inverse limits in [31, sec. 3.5] apply. In particular, if there is an inverse system

$$\cdots \to M^2 \xrightarrow{\mu^2} M^1 \xrightarrow{\mu^1} M^0,$$

then there is an exact sequence

$$0 \to \varprojlim M^i \to \prod_i M^i \xrightarrow{\text{id} - \text{shift}} \prod_i M^i \to R^1 \varprojlim M^i \to 0,$$

where $\text{id} - \text{shift}$ is the difference between the identity morphism and the shift morphism induced by the $\mu^i$.

The inverse system is said to satisfy the Mittag-Leffler condition if, for each $i \geq 0$, the images of the maps $M^\ell \to M^i$ for $\ell \geq i$ satisfy the descending chain condition. In this case we have $R^1 \varprojlim M^i = 0$. This holds in particular if each morphism in (A.5) is an epimorphism.

If there is a short exact sequence

$$\begin{array}{cccccccc}
\cdots & \to & M'^2 & \xrightarrow{} & M'^1 & \xrightarrow{} & M'^0 & \\
\downarrow & & \downarrow & & \downarrow & & \downarrow & \\
\cdots & \to & M'^2 & \xrightarrow{} & M'^1 & \xrightarrow{} & M'^0 & \\
\downarrow & & \downarrow & & \downarrow & & \downarrow & \\
\cdots & \to & M'^2 & \xrightarrow{} & M'^1 & \xrightarrow{} & M'^0 & \\
\downarrow & & \downarrow & & \downarrow & & \downarrow & \\
\cdots & \to & M'^2 & \xrightarrow{} & M'^1 & \xrightarrow{} & M'^0 & \\
\end{array}$$

of inverse systems, then there is an induced long exact sequence

$$0 \to \varprojlim M'_i \to \varprojlim M_i \to \varprojlim M''_i \to R^1 \varprojlim M'_i \to R^1 \varprojlim M_i \to R^1 \varprojlim M''_i \to 0.$$ 

If each morphism in the $M'$-system is an epimorphism, then $R^1 \varprojlim M'_i = 0$ and there is a short exact sequence

$$0 \to \varprojlim M'_i \to \varprojlim M_i \to \varprojlim M''_i \to 0.$$ 

Some of the results on inverse limits in [12, sec. 6] also apply. In particular, the Lukas Lemma says that if $N$ is fixed, then in order to conclude $\varprojlim M^i \in N^\perp$, it is enough to verify the following for the inverse system (A.5), see [12, lem. 6.37].

(i) $\mu^i$ is an epimorphism for $i \geq 1$.

(ii) $M^0 \in N^\perp$.

(iii) $\text{Ker} \mu^i \in N^\perp$ for $i \geq 1$.

A.8 (The radical filtration). If $i \geq 0$ then the $i$'th power of the radical, $\text{rad}_Q^i(-,-)$, is an object of $Q\text{Mod}_Q$. Because of condition (Rad) of Definition 2.3, there is a finite filtration in $Q\text{Mod}_Q$,

$$0 = \text{rad}_Q^N \subseteq \cdots \subseteq \text{rad}_Q^1 \subseteq \text{rad}_Q^0 = Q(-,-),$$

where $N \geq 0$ is chosen minimal such that $\text{rad}_Q^N = 0$. Each quotient $\text{rad}_Q^i / \text{rad}_Q^{i-1}$ is annihilated on both sides by $\text{rad}_Q$, and this implies

$$\text{rad}_Q^i / \text{rad}_Q^{i-1} \cong \prod_{p,q} (\text{DS}(p) \otimes S(q))^{n_i(p,q)}$$

for certain integers $n_i(p,q)$. 

Acknowledgement. We thank an anonymous referee for reading the paper carefully and making a number of useful suggestions.

We thank Jim Gillespie, Osamu Iyama, Berhard Keller, Sondre Kvamme, and Hiroyuki Minamoto for a number of illuminating comments, and Bernhard Keller for pointing out references \[8\] and \[22\].

This work was supported by EPSRC grant EP/P016014/1 “Higher Dimensional Homological Algebra” and LMS Scheme 4 Grant 41664.
