DETERMINANTAL IDEALS AND THE CANONICAL COMMUTATION RELATIONS. CLASSICALLY OR QUANTIZED

HANS PLESNER JAKOBSEN

Abstract. We construct homomorphic images of $su(n,n)\mathbb{C}$ in Weyl Algebras $\mathcal{H}_{2nr}$. More precisely, and using the Bernstein filtration of $\mathcal{H}_{2nr}$, $su(n,n)\mathbb{C}$ is mapped into degree 2 elements with the negative non-compact root spaces being mapped into second order creation operators. Using the Fock representation of $\mathcal{H}_{2nr}$, these homomorphisms give all unitary highest weight representations of $su(n,n)\mathbb{C}$ thus reconstructing the Kashiwara–Vergne List for the Segal–Shale–Weil representation. Just as in the derivation of the their list, we construct a representation of $u(r)$ in the Fock space commuting with $su(n,n)\mathbb{C}$, and this gives the multiplicities. The construction also gives an easy proof that the ideals of $(r+1)\times(r+1)$ minors are prime ($r \leq n-1$). The quotients of all polynomials by such ideals carry the more singular of the representations. As a consequence, these representations can be realized in spaces of solutions to Maxwell type equations. We actually go one step further and determine exactly which representations from our list are missing some $\mathfrak{f}\mathbb{C}$-types, thereby revealing exactly which covariant differential operators have unitary null spaces.

We prove the analogous results for $U_q(su(n,n)\mathbb{C})$. The Weyl Algebras are replaced by the Hayashi–Weyl Algebras $\mathcal{H}W_{2nr}$ and the Fock space by a $q$-Fock space. Further, determinants are replaced by $q$-determinants, and a commuting representation of $U_q(u(r))$ in the $q$-Fock space is constructed. For this purpose a Drinfeld Double is used. We mention one difference: The quantized negative non-compact root spaces, while still of degree 2, are no longer given entirely by second order creation operators.

1. INTRODUCTION

The most fundamental equation in analysis must be

$$\left[ \frac{d}{dx}, x \right] = 1.$$  (1.1)

The algebraic structure corresponding to this is the Weyl Algebra. By inserting an $i$ in the equation it becomes the “canonical commutation relation” of mathematical physics. Another, equivalent way is to define the annihilator operator $A = \frac{1}{\sqrt{2}}(x + \frac{d}{dx})$. Its (formal) adjoint is $A^\dagger = \frac{1}{\sqrt{2}}(x - \frac{d}{dx})$ and is known as the creation operator. We have of course

$$[A, A^\dagger] = 1.$$  (1.2)

The Metaplectic Group is the automorphism group of this equation.

In the very first studies of the metaplectic representation by L. van Hove, the representation was given on the Lie algebra level. See ([44]), the summary ([44]), as well as the review by I. E. Segal ([39]). However, in subsequent studies by D. Shale ([41]) (see also

2020 Mathematics Subject Classification. MSC 17B37 (primary), MSC 20G42 (primary), MSC 20G45 (primary), MSC 81Q12 (primary) MSC 14M12 (primary), MSC 16T10 (secondary), MSC 81R50 (secondary), MSC 81Q05 (secondary), MSC 81Q10 (secondary) and MSC 81R05 (secondary).
The emphasis was shifted to the group level. Here, the representation was called the Segal-Shale-Weil (or harmonic) representation.

This shift makes it easy to explain the basic observations yielding a unitary representation of the Metaplectic Group $Mp(n, \mathbb{R})$ (a 2-fold cover of $Sp(n, \mathbb{R})$): I) By the Stone–von Neumann Theorem ([43], [46]) there is an essentially unique non-trivial irreducible representation of the Heisenberg Group $H_n$; $H_n \ni h \mapsto \pi(h)$. II) Any $g \in Sp(n, \mathbb{R})$, appropriately interpreted, acts as an automorphism of $H_n$. Hence there must be a unitary operator $T(g)$ such that $\pi(g(h)) = T(g) \pi(h) T(g)^{-1}$. The operator is not unique and therefore we do not immediately get a representation of $Sp(n, \mathbb{R})$, but it may be seen that this obstacle may be removed by passing to $Mp(n, \mathbb{R})$ (cf. [26]).

The infinitesimal version of this seems less well known though occasionally touched upon in connection with the mathematical treatment of the quantum mechanical harmonic operator. The author learned about this representation from his masters advisor who, among many other things, studied the canonical commutation relations (see ([35]).

The infinitesimal level has the pleasing feature of building everything from the fundamental operators $x$ (as multiplication operator) and $\frac{\partial}{\partial x}$. Of course, one can extend to several, indeed many, variables.

The Weyl algebra is defined as $H_1 = \text{Span}_\mathbb{C}\{A^r, (A^\dagger)^s \mid r, s \in \mathbb{N}_0\}$. It is also the enveloping algebra of the Heisenberg group, hence the symbol. The Weyl algebra $H_s$ is just the product of $s$ copies of $H_1$. Likewise, the so-called (by physicists) Fock space $F_s$ of $H_s$ is generated by a cyclic vector $v_s$ which is annihilated by all elements $A_i, i = 1, \ldots, s$. The algebra acts by the natural left action yielding the Stone–von Neumann representation $\pi_{S\text{vN}}^s$. It is easy to see, and well known, that $\pi_{S\text{vN}}^s$ is injective on $H_s$. These simple (in many ways) representations yield all unitarizable highest weight representations of $su(n, n)^\mathbb{C}$.

The idea is again to use the Stone–von Neumann theorem while observing that the inclusion $su(n, n)^\mathbb{C} \hookrightarrow sp(2n, \mathbb{R})^\mathbb{C}$ yields derivations of the Weyl algebra. These are known to be inner.

In the end it turns out, however, that one can construct the homomorphisms $su(n, n)^\mathbb{C} \rightarrow H_{2nr}$ directly.

This is the path we take.

The assignments

$$e = \frac{i}{2} A^2, \quad f = \frac{i}{2} (A^\dagger)^2, \quad h = [e, f]$$  (1.3)

defines a representation of $sl(2, \mathbb{C}) = sp(1, \mathbb{R}) = su(1, 1)^\mathbb{C}$.

To explain some further details, let us consider $H_4$. The following elements

$$W_{1,1} = A_4^\dagger A_3^\dagger, \quad W_{1,2} = A_4^\dagger A_1^\dagger,$$

$$W_{2,1} = A_3^\dagger A_4^\dagger, \quad W_{2,2} = A_2^\dagger A_4^\dagger$$  (1.4)

generate a polynomial subalgebra $U_{0-} \subset H_4$. They can be seen to correspond to the negative non-compact roots of $su(2, 2)$, where e.g. $W_{1,1}$ is the root vector $f_\beta$ for
the unique non-compact simple root $\beta$. The positive non-compact roots are given by analogously quadratic expressions in annihilation operators. Clearly, there is a non-trivial relation

$$W_{1,1}W_{2,2} = W_{2,1}W_{1,2}, \quad (1.6)$$

and this is the equation for the vanishing of the determinant, $\det W = 0$ of the $2 \times 2$ matrix $W$ whose entries are the above $W_{i,j}; i, j = 1, 2$.

This implies that

$$U_0^- \simeq \mathcal{P}(W_{1,1}W_{1,2}W_{2,1}W_{2,2})/\mathcal{I}_{2 \times 2} \quad (1.7)$$

where $\mathcal{P} = \mathcal{P}(W_{1,1}W_{1,2}W_{2,1}W_{2,2})$ is the full polynomial algebra in 4 variables and $\mathcal{I}_{2 \times 2}$ is the ideal generated by $\det W$. Since $U_0^-$ is a subalgebra of the algebra of polynomials in $A^\dagger_i, i = 1, 2, 3, 4$, this easily implies that $\mathcal{I}_{2 \times 2}$ is a prime ideal.

More generally, using the same method, we can prove

**Theorem 3.26** The ideal generated by all $k \times k$ minors of an $r \times r$ matrix is prime.

This result is due to K. R. Mount ([33]), but see also the discussion in the end of Chapter 2 ([4]).

Returning to the $2 \times 2$ case, one can easily decompose the full Fock representation: Consider $\forall N, S \in \mathbb{N}_0$ the spaces

$$V_N^\uparrow = \text{Span}_\mathbb{C}\{(A_1^\dagger)^i(A_2^\dagger)^j | i + j = N\}, \quad (1.8)$$

$$V_N^\downarrow = \text{Span}_\mathbb{C}\{(A_3^\dagger)^i(A_4^\dagger)^j | i + j = S\}. \quad (1.9)$$

Then the spaces $U_0^- \otimes V_N^\uparrow$ and $U_0^- \otimes V_S^\downarrow$ carry unitarizable irreducible highest weight modules, and together they furnish a decomposition of the Fock representation.

In the analogous case for $su(n, n)^C$ one has the Kashiwara–Vergne List of unitarizable highest weight modules. Recall that it was conjectured by Kashiwara and Vergne and proved by the current author in ([17]) that this list describes all irreducible, unitarizable highest weight modules. A key point in the proof of this result was the Bernstein–Gelfand–Gelfand Theorem ([2]) and the last possible place of unitarity ([17]). This was applied to the already constructed list. In the current study we bring this one step further and use these same tools to actually construct the list. Further ingredients are: missing $t^C$-types (covariant differential operators), and tensor products of generalized Verma modules.

In comparison to Kashiwara–Vergne, we actually go one step further and determine exactly which representations from our list are missing some $t^C$-types, thereby revealing exactly which covariant differential operators have unitary null spaces.

We will refer to the above as the “classical case”, the “classical results”, or sometimes even the “$q = 1$ case” when discussing the “quantized case”.

In 1990, T. Hayashi ([16]) introduced a number of very important quantum algebras and studied some basic representations of these. In his families are both quantized symplectic as well as quantized spinor representations. His method and construction is clearly the right way to quantize the harmonic representation, and will form the foundation of our investigations in the case of $U_q(su(n, n)^C)$. This case was not covered by him.

The case of the quantized enveloping algebra proceeds along similar lines, though there occurs some additional technicalities.
First of all, the basic algebras are now the Hayashi-Weyl Algebras $\mathcal{HW}_{s}$, $s \in \mathbb{N}$: Let $q$ be a non-zero complex number such that $q^2 \neq 1$. The algebra $\mathcal{HW}_1$ is defined as an associative unital algebra with generators $B, L, L^{-1}$ and relations

\begin{align*}
LL^{-1} &= L^{-1}L = 1, \quad (1.10) \\
LBL^{-1} &= q^{-1}B, \quad LB^\dagger L^{-1} = qB^\dagger, \quad (1.11) \\
BB^\dagger - qB^\dagger B &= L^{-1}, \quad BB^\dagger - q^{-1}B^\dagger B = L. \quad (1.12)
\end{align*}

$\mathcal{HW}_s$ is the product of $s$ copies of $\mathcal{HW}_1$.

These algebras are of fundamental importance. Early on, these algebras were studied in ([36]), recently a renewed interest has been observed ([25]), see also ([21]).

The definition of the $q$-Fock spaces $\mathcal{F}^{(q)}_{2nr}$ and $q$-Stone-von Neumann representation $π_{qSvN}$, $r = 1, \ldots$, are then straightforward.

We obtain the analogues of the classical results for this algebra. Specifically, we construct homomorphisms $U_q(su(n,n)) \rightarrow \mathcal{HW}_{2nr}$, $r \in \mathbb{N}$ The homomorphisms are more complicated. While still of degree 2, one needs in general both creation and annihilation operators to describe the (quantized) negative non-compact root spaces. For the treatment here, we rely on representation theory as developed in ([34]) and ([38]). In ([34]) can also be found definitions and fundamental results relating to $q$-determinants.

We then obtain the following result which was first proved in ([27]).

**Theorem 5.64** The $q$-determinantal ideals are prime.

As for the decomposition of the quantized Fock spaces $F^{(q)}_{2nr}$, $r = 1, 2, \ldots$, one has to construct a representation of $U_q(u(r))$ on $F^{(q)}_{2nr}$ which commutes with the action of $U_q(su(n,n))$ and even with $U_q(u(n,n))$. Here we rely on ([34]). The construction actually results in a Drinfeld Double. In the end, a result analogous to the classical case is obtained. We call the result the quantized Kashiwara-Vergne List. This result is more descriptive than a mere claim of “similar representation theory” because it constructs explicitly the highest weight vectors in terms of quantum minors.

We finish the last section by making a few remarks about “quantized wave operators”.

The topics we discuss here have been studied previously by many authors, and may easily be seen as special cases, pushed a bit further, of many studies. We will not try to be comprehensive but will mention just two: ([9]) and ([28]).

The results were first announced at the conference Quantum Groups, Quantum Symmetric Spaces, and Operator Algebras, Kristineberg 2-8 June 2019, organized by L. Turovska, A. Stolin, and G. Zhang to the memory of Leonid Vaksman. We were glad for the opportunity to pay homage.

Besides this introduction, the material is arranged into the following five sections: §2: The (quantized) enveloping algebras, §3: The harmonic representation in the classical case, §4: The Kashiwara-Vergne list of unitary representations, §5: The $q$-harmonic representation. §6: The full decomposition of the $q$-Fock spaces.
2. The (Quantized) Enveloping Algebras

We consider \( \mathfrak{g}^C = su(n,n)^C \). The simple roots are denoted \( \Pi = \{ \mu_1, \ldots, \mu_{n-1} \} \cup \{ \beta \} \cup \{ \nu_1, \ldots, \nu_{n-1} \} \), where \( \beta \) is the unique non-compact root. We have

\[
\mathfrak{g}^C = \mathfrak{t}^C \oplus \mathfrak{p}^C = \mathfrak{p}^- \oplus \mathfrak{t}^C \oplus \mathfrak{p}^+, \tag{2.1}
\]

\( \zeta \) is the center, \( \mathfrak{p}^\pm \) are abelian \( \mathcal{U}(\mathfrak{t}^C) \) modules, \( [\mathfrak{p}^+, \mathfrak{p}^-] \subseteq \mathfrak{t}^C \), and \( \mathcal{U}(\mathfrak{g}^C) = \mathcal{P}(\mathfrak{p}^-) \cdot \mathcal{U}(\mathfrak{t}^C) \cdot \mathcal{P}(\mathfrak{p}^+) \).\tag{2.2}

The subalgebras \( \mathfrak{t}^C_{\mu}, \mathfrak{t}^C_{\nu} \) above are generated by the simple roots \( \{ \mu_1, \ldots, \mu_{n-1} \} \), and \( \{ \nu_1, \ldots, \nu_{n-1} \} \), respectively. Later we will also use the terminology \( \mathfrak{t}^C_{\mu} = \mathfrak{t}^C_L \) and \( \mathfrak{t}^C_{\nu} = \mathfrak{t}^C_R \).\tag{2.3}

The generators are denoted by \( E_\alpha, F_\alpha \), and we set \( h_\alpha = [E_\alpha, F_\alpha] \), for \( \alpha \in \Pi \).

For later use, we fix the imbedding \( su(n,n) \hookrightarrow gl(n, \mathbb{C}) \) by the hermitian form \( J = \begin{pmatrix} I_n & 0 \\ 0 & -I_n \end{pmatrix} \). This means that \( X \in su(n,n) \Leftrightarrow X^*J + JX = 0 \). As a consequence, we choose the traceless diagonal matrices as our (compact) Cartan subalgebra. We choose further \( \mu_i = \varepsilon_i - \varepsilon_{i+1}, i = 1, \ldots, n-1 \), and \( \nu_i = \varepsilon_{n+i} - \varepsilon_{n+i+1}, i = 1, \ldots, n-1 \), and \( \beta = \varepsilon_n - \varepsilon_{n+1} \). We write a weight \( \Lambda = (\Lambda_\mu, \Lambda_\nu, \lambda_\beta) \) in accordance with this. For specificity, \( \lambda_\beta := \Lambda(h_\beta) \). Furthermore, \( \Lambda_\mu = (n_1, n_2, \ldots, n_n) \in \mathbb{Z}^n \) and \( \Lambda_\nu = (m_1, m_2, \ldots, m_n) \in \mathbb{Z}^n \). We have that \( n_1 \geq n_2 \geq \cdots \geq n_n \) and likewise \( m_1 \geq m_2 \geq \cdots \geq m_n \). Then \( \Lambda_\mu(\mu_i) = n_i - n_{i+1}, i = 1, \ldots, n-1 \) and \( \Lambda_\nu(\nu_j) = m_j - m_{j+1}, j = 1, \ldots, n-1 \). Notice that we do not insist that \( n_n \geq 0 \) or \( m_n \geq 0 \), which turns out to be convenient. One can always find a representative in an equivalence class for which this holds. Here, two \( n \) tuples in \( \mathbb{Z}^n \) are equivalent if they differ by the addition of some \( (p, p, \ldots, p) \). Equivalent tuples define the same module. Notice: We make no coupling between these integers and \( h_\beta \).

\( \mathcal{P}^\pm := \mathcal{P}(\mathfrak{p}^\pm) = \mathcal{U}(\mathfrak{p}^\pm) \) are polynomial algebras, given explicitly as

\[
\mathcal{P}^+ = \mathbb{C}[Z_{i,j} \mid i, j = 1, \ldots, n], \tag{2.4}
\]

\[
\mathcal{A}^+ = \mathbb{C}[W_{i,j} \mid i, j = 1, \ldots, n], \tag{2.5}
\]

where

\[
Z_{i,j} = \text{ad}(E_{\nu_i-1}) \ldots \text{ad}(E_{\nu_0}) \cdot \text{ad}(E_{\mu_i-1}) \ldots \text{ad}(E_{\mu_0})(E_\beta), \tag{2.6}
\]

\[
W_{i,j} = \text{ad}(E_{\nu_i-1}) \ldots \text{ad}(E_{\nu_0}) \cdot \text{ad}(F_{\mu_i-1}) \ldots \text{ad}(F_{\mu_0})(F_\beta). \tag{2.7}
\]

Above, for convenience, we set \( \text{ad}(F_{\mu_0}) = \text{ad}(F_{\nu_0}) = I \).

In the quantum group \( \mathcal{U}_q(\mathfrak{g}^C) \), we denote the generators by \( E_\alpha, F_\alpha, K_\alpha^{\pm 1} \) for \( \alpha \in \Pi \). There are also decompositions

\[
\mathcal{U}_q(\mathfrak{g}^C) = \mathcal{A}_q^- \cdot \mathcal{U}_q(\mathfrak{t}^C) \cdot \mathcal{A}_q^+, \tag{2.8}
\]

\[
\mathcal{U}_q(\mathfrak{t}^C) = \mathcal{U}_q(\mathfrak{t}^C_L) \cdot \mathbb{C}[K_\beta^{\pm 1}] \cdot \mathcal{U}_q(\mathfrak{t}^C_R). \tag{2.9}
\]
Here, $A^\pm_q$ are quadratic algebras which are furthermore $\mathcal{U}_q(t^\mathbb{C})$ modules. Specifically,

$$A^-_q = \mathbb{C}[W_{ij} \mid i, j = 1, \ldots, n], \text{ and}$$

$$A^+_q = \mathbb{C}[Z_{ij} \mid i, j = 1, \ldots, n],$$

with relations in $A^-_q$ given by (these are the relations of the so-called “standard” quantized matrix algebra discovered in ([10]));

$$FRT(q^{-1}):$$

$$W_{ij}W_{ik} = q^{-1}W_{ik}W_{ij} \text{ if } j < k,$$

$$W_{ij}W_{kj} = q^{-1}W_{kj}W_{ij} \text{ if } i < k,$$

$$W_{ij}W_{st} = W_{st}W_{ij} \text{ if } i < s \text{ and } t < j,$$

$$W_{ij}W_{st} = W_{st}W_{ij} - (q - q^{-1})W_{it}W_{sj} \text{ if } i < s \text{ and } j < t.$$

The algebra $A^+_q$ has the same relations, but the algebras $A^\pm_q$ are different as $\mathcal{U}_q(t^\mathbb{C})$ modules. The elements $Z_{ij}$ and $W_{ij}$ are constructed by means of the Lusztig operators. References [30] and [23] are general references of much of this. Using the Serre relations one gets, setting $\mu_0 = Id$,

Lemma 2.1.

$$Z_{ij} = T_{v_{j-1}}T_{v_{j-2}} \cdots T_{v_0} \cdot T_{\mu_{i-1}}T_{\mu_{i-2}} \cdots T_{\mu_0}(E_{\beta}), \text{ and}$$

$$W_{ij} = (-q^{-1})^{i+j-2}T_{v_{j-1}}T_{v_{j-2}} \cdots T_{v_0} \cdot T_{\mu_{i-1}}T_{\mu_{i-2}} \cdots T_{\mu_0}(F_{\beta}).$$

On simple roots $\alpha, \gamma$ one has

$$T_{\alpha}(E_{\gamma}) = E_{\alpha}E_{\gamma} - q^{-1}E_{\gamma}E_{\alpha}, \text{ and}$$

$$T_{\alpha}(F_{\gamma}) = F_{\gamma}F_{\alpha} - qF_{\alpha}F_{\gamma}. \quad \text{(2.16)}$$

Remark 2.2. The factor $(-q^{-1})^{i+j-2}$ is inserted to make the formulas have a nice limit for $q = 1$. It leads to the same relations as those for elements $\tilde{W}_{ij} = (-q^{-1})^{-i-j+2}W_{ij}$ defined without the factor. The latter choice has been preferred in our previous articles.

We now recall the definition of a quantum minor from [34]:

Suppose $I = \{i_1 < i_2 < \cdots < i_m\}$ and $J = \{j_1 < j_2 < \cdots < j_m\}$ are subsets of $I = \{1, 2, \ldots, \min\{r, s\}\}$. Define

$$\det_a(I, J) = \sum_{\sigma \in S_m} (-a)^{l(\sigma)} w_{i_{\sigma(1)}j_{\sigma(1)}} w_{i_{\sigma(2)}j_{\sigma(2)}} \cdots w_{i_{\sigma(m)}j_{\sigma(m)}} \quad \text{(2.17)}$$

These elements are called quantum $m \times m$ minors. The parameter $a$ depends on the relations. The relations in ([34]) are obtainable from the relations (2.12) by interchanging $q \leftrightarrow q^{-1}$. The $q$-determinants of ([34]) are then those denoted by $\det_q$ whereas quantum minors in our setting will be taken as $\det_q$. We will also set...
\[
\det_a(I, J) = \det_a \left( \begin{array}{c}
w_{i_1,j_1} \cdots w_{i_n,j_n} \\
\vdots & \vdots \\
w_{i_m,j_1} \cdots w_{i_m,j_m}
\end{array} \right). \tag{2.19}
\]

In particular, we set
\[
\triangle_{a,m}(w) = \det_a \left( \begin{array}{c}
w_{1,1} \cdots w_{1,m} \\
\vdots & \vdots \\
w_{m,1} \cdots w_{m,m}
\end{array} \right). \tag{2.20}
\]

3. The harmonic representation in the classical case

3.1. The Weyl algebras. The Weyl algebra \( \mathcal{H}_1 = \text{Span}_\mathbb{C}\{A^r, (A\dagger)^s \mid r, s \in \mathbb{N}_0\} \) is defined in terms of the Heisenberg canonical commutation relations:
\[
[A, A\dagger] = I, \tag{3.1}
\]

and the Weyl algebra \( \mathcal{H}_s \) is just the product of \( s \) copies of \( \mathcal{H}_1 \).

Lemma 3.1.
\[
\begin{align*}
[A A\dagger, A\dagger] & = A\dagger \tag{3.2} \\
[AA\dagger, A] & = -A. \tag{3.3}
\end{align*}
\]

Lemma 3.2.
\[
\forall s \in \mathbb{N}_0 : AA\dagger(A\dagger)^s = (s + 1)(A\dagger)^s + (A\dagger)^{s+1}A \tag{3.4}
\]

A simple but key result:

Lemma 3.3 (The Weyl-Serre Equations).
\[
\begin{align*}
(A\dagger)^2 A - 2(A\dagger AA\dagger) + A(A\dagger)^2 & = 0 \tag{3.5} \\
A^2 A\dagger - 2(AA\dagger A) + A\dagger A^2 & = 0 \tag{3.6}
\end{align*}
\]

3.2. \( \mathfrak{su}(n,n) \). We now consider specifically the Weyl algebra
\[
\mathcal{H}_{2n} = \text{Span}_\mathbb{C}\{A^r_i, (A\dagger)^s_j \mid i, j = 1, \ldots, 2n, r, s \in \mathbb{N}_0\}. \tag{3.7}
\]

It is defined in terms of the Heisenberg canonical commutation relations:
\[
\begin{align*}
[A_k, A_\ell] & = 0, \tag{3.8} \\
[A_k\dagger, A_\ell\dagger] & = 0, \text{ and} \tag{3.9} \\
[A_k, A_\ell\dagger] & = \delta_{k,\ell}. \tag{3.10}
\end{align*}
\]

Throughout \( \S3 \) and \( \S4 \), \( \mathfrak{su}(n,n) \) is fixed, and \( n \) will be suppressed whenever it is convenient.
Definition 3.4.
\[
\begin{align*}
F^{(1)}_{\beta} &= A_1^\dagger A_{n+1}^\dagger, & E^{(1)}_{\beta} &= -A_1 A_{n+1}, \\
H^{(1)}_{k} &= A_k^\dagger A_k, & H^{(1)}_{\beta} &= -H^{(1)}_1 - H^{(1)}_{n+1}, \\
F^{(1)}_{\mu_k} &= A_{k+1}^\dagger A_k, & E^{(1)}_{\mu_k} &= A_{k+1} A_k^\dagger, \\
F^{(1)}_{\nu_{\ell}} &= A_{n+\ell} A_{n+\ell+1}^\dagger, & E^{(1)}_{\nu_{\ell}} &= A_{n+\ell}^\dagger A_{n+\ell+1}, \\
H^{(1)}_{\mu_k} &= H^{(1)}_k - H^{(1)}_{k+1}, & H^{(1)}_{\nu_{\ell}} &= H^{(1)}_{n+k} - H^{(1)}_{n+k+1}.
\end{align*}
\]

Definition 3.5.
\[
\Xi = \sum_{k=1}^{n} A_k^\dagger A_k - \sum_{k=n+1}^{2n} A_k^\dagger A_k. \quad (3.11)
\]

Proposition 3.6. The elements in Definition 3.4 satisfy the Serre relations for \(su(n, n)^\mathbb{C}\). The element \(\Xi\) commutes with all of these.

Proof. This follows easily from (3.6). \(\square\)

Remark 3.7. The form of the elements \(H_*\) turns out to be convenient for what follows. The unusual form can be recast into a more familiar one using elements \(h_i = -A_i A_i^\dagger; i = 1, \ldots, n\) and \(h_i = A_i^\dagger A_i; i = n + 1, \ldots, 2n\).

Corollary 3.8. The relations above define a homomorphism
\[
\psi^{(1)}_q : \mathcal{U}(su(n, n)^\mathbb{C}) \to \mathcal{H}_{2n}. \quad (3.12)
\]

Definition 3.9.
\[
W^{(1)}_{k, \ell} = A_k^\dagger A_{n+\ell}^\dagger \text{ and } Z^{(1)}_{k, \ell} = -A_k A_{n+\ell}. \quad (3.13)
\]

Lemma 3.10. For \(k, \ell < n\),
\[
W^{(1)}_{k+1, \ell} = F_{\mu_k} W^{(1)}_{k, \ell} - W^{(1)}_{k, \ell} F_{\mu_k} \text{ and } W^{(1)}_{k, \ell+1} = F_{\nu_{\ell}} W^{(1)}_{k, \ell} - W^{(1)}_{k, \ell} F_{\nu_{\ell}}.
\]

Proof. This follows from the definitions along with (3.8, 3.10). \(\square\)

3.3. Unitarity; Stone–von Neumann. The (infinitesimal) Stone–von Neumann representation \(\pi^{\text{StN}}_1\) (by physicists often called the Fock representation) is the irreducible unitary representation of \(\mathcal{H}_1\) in a Hilbert space \(\mathcal{F}_1\) defined in terms of a cyclic vector \(v_1\) called the vacuum vector which is annihilated by \(A\). (\(A\) is an annihilation operator.)

Specifically,
\[
A v_1 = 0, \text{ and } \quad (3.14)
\]
\[
\mathcal{F}_1 = \text{Span}_\mathbb{C}\{(A^\dagger)^r v_1 \mid r \in \mathbb{N}_0\}. \quad (3.15)
\]
More generally, there is the analogous unitary representation \( \pi_{s}^{SvN} \) of \( H_{s} \) in \( \mathcal{F}_{s} = \mathcal{U}^{-}(H_{s}) \). This is just the (outer) tensor product of \( s \) copies of \( \pi_{1}^{SvN} \). We denote by \( v_{s} \) the \( s \) fold tensor product of \( v_{1} \).

Here, \( \mathcal{U}^{-}(H_{s}) \) denotes the subalgebra generated by all creation operators.

**Proposition 3.11.** \( \pi_{s}^{SvN} \) is an irreducible representation of \( \mathcal{U}(H_{s}) \).

**Proof:** \( H_{s} \) acts as shift operators, omitting no positions. \( \square \)

**Proposition 3.12.** Let \( 0 \neq v \in F_{s} \). For \( p \in \mathcal{U}^{-}(H_{s}) \) it holds that
\[
p \cdot v = 0 \iff p \cdot v_{s} = 0 \iff p = 0.
\]

**Proof:** This follows since \( \mathcal{U}^{-}(H_{s}) \) is a polynomial (abelian) algebra.

Even more holds:

**Proposition 3.13.** Let \( p \in \mathcal{U}^{-}(H_{s}) \) and \( v \in F_{s} \). Then
\[
p \cdot v = 0 \iff [p = 0 \lor v = 0]
\]

**Proof:** Using a standard monomial basis \( \{X^{a}\} \) of \( \mathcal{U}^{-}(H_{s}) \) we can write
\[
p \cdot v_{s} = \sum_{b} \beta_{b}(A^{\dagger})^{b} \cdot v_{s} \text{ and } v = \sum_{a} \alpha_{a}(A^{\dagger})^{a} \cdot v_{s}.
\]

Then
\[
p \cdot v = \sum_{a} \alpha_{a}(A^{\dagger})^{a} \cdot p \cdot v_{s} = \sum_{a,b} \alpha_{a} \beta_{b}(A^{\dagger})^{a+b} \cdot v_{s}.
\]

By using some (lexicographic) order and focusing in highest order terms, it follows easily that either \( \forall a : \alpha_{a} = 0 \) or \( \forall b : \beta_{b} = 0 \). \( \square \)

### 3.4. Prime. 2 × 2 minors.

**Lemma 3.14.** Let \( W^{(1)} \) be the \( n \times n \) matrix whose \( i,j \) entry is \( W_{i,j}^{(1)} \). Then any \( 2 \times 2 \) minor vanishes.

**Proof.** This follows easily since the product of the diagonal elements equals the product of the off diagonal elements. Alternatively, set
\[
X^{(1)} = \begin{pmatrix} A_{1}^{\dagger} \\ A_{2}^{\dagger} \\ \vdots \\ A_{n}^{\dagger} \end{pmatrix} \quad \text{and} \quad Y^{(1)} = \begin{pmatrix} A_{1}^{\dagger} \\ A_{n+1}^{\dagger} \\ \vdots \\ A_{2n}^{\dagger} \end{pmatrix}.
\]

Then \( W^{(1)} = X^{(1)} \cdot (Y^{(1)})^{T} \), so \( W^{(1)} \) is rank 1.

**Definition 3.15.** Let \( \mathcal{P} \) denote the complex algebra generated by \( n^{2} \) commuting entries \( W_{ij} \) of a complex \( n \times n \) matrix \( W \), and let \( \mathcal{P}^{(1)} \) denote the complex algebra generated by the above \( n^{2} \) commuting variables \( W_{ij}^{(1)} \). Finally, let \( \mathcal{I}_{2 \times 2} \) denote the ideal in \( \mathcal{P} \) generated by all \( 2 \times 2 \) minors of \( W \).
The following is, for the first part obvious, and for the rest, well-known:

**Lemma 3.16.** The spaces \( \mathcal{P}^{(1)}, \mathcal{P}, \) and \( \mathcal{I}_{2 \times 2} \) are \( \mathfrak{k} \times \mathfrak{k} \) modules.

**Proposition 3.17.**

\[
\mathcal{P}^{(1)} = \mathcal{P}/\mathcal{I}_{2 \times 2}. \tag{3.21}
\]

**Proof.** We have a natural homomorphism \( \Phi^{(1)} : \mathcal{P} \to \mathcal{P}^{(1)} \) given on generators by \( W_{ij} \to W_{ij}^{(1)} \). The kernel of \( \Phi^{(1)} \) contains \( \mathcal{I}_{2 \times 2} \), but must in fact equal since both spaces decompose in the same way under \( \mathfrak{k} \times \mathfrak{k} \). Specifically, the highest weight vectors for \( \mathfrak{k} \times \mathfrak{k} \) in \( \mathcal{P}^{(1)} \) are the elements \( \left(W_{1,1}^{(1)} \right)^r ; r = 1, 2, \cdots \) \( \square \)

The following theorem is then obtained:

**Theorem 3.18.** The ideal \( \mathcal{I}_{2 \times 2} \) is prime.

**Proof.** Let \( p_{1}^{(1)}, p_{2}^{(1)} \in \mathcal{P}^{(1)} \) satisfy \( p_{1}^{(1)} \cdot p_{2}^{(1)} = 0 \). We can assume that \( p_{i}^{(1)} \cdot v_{s} \neq 0, \ i = 1, 2, \) and \( p_{1}^{(1)} \cdot p_{2}^{(1)} \cdot v_{s} = 0 \). This contradicts Proposition 3.13. \( \square \)

3.5. **Rank r.** One can make an analogous construction based on \( \mathfrak{h}_{2nr} \): We label the elements as \( A_{i}^{(s)}, (A_{i}^{(s)})^{\dagger}, i = 1, \ldots, 2n \) and \( s = 1, \ldots, r \).

**Definition 3.19.** Set

\[
F_{\beta}(r) = \sum_{s=1}^{r} (A_{1}(s))^{\dagger} (A_{n+1}(s))^{\dagger}, \quad E_{\beta}^{(r)} = -\sum_{s=1}^{r} (A_{1}(s))(A_{n+1}(s)), \tag{3.22}
\]

\[
F_{\mu_{k}}^{(r)} = \sum_{s=1}^{r} (A_{k+1}(s))^{\dagger}(A_{k}(s))^{\dagger}, \quad E_{\mu_{k}}^{(r)} = \sum_{s=1}^{r} (A_{k+1}(s))(A_{k}(s))^{\dagger}, \tag{3.23}
\]

\[
F_{\nu_{\ell}}^{(r)} = \sum_{s=1}^{r} (A_{n+\ell}(s))(A_{n+\ell+1}(s))^{\dagger}, \quad E_{\nu_{\ell}}^{(r)} = \sum_{s=1}^{r} (A_{n+\ell}(s))^{\dagger}(A_{n+\ell+1}(s)). \tag{3.24}
\]

\[
H_{k}^{(r)} = \sum_{s=1}^{r} (A_{k}^{\dagger}(s))(A_{k}(s)), \tag{3.25}
\]

\[
H_{\mu_{k}}^{(r)} = \sum_{i=1}^{r} A_{k}^{\dagger}(i)A_{k}(i) - \sum_{i=1}^{r} A_{k-1}^{\dagger}(i)A_{k-1}(i), k = 1, \ldots, n - 1, \tag{3.26}
\]

\[
H_{\nu_{k}}^{(r)} = \sum_{i=1}^{r} A_{n+k}^{\dagger}(i)A_{n+k}(i) - \sum_{i=1}^{r} A_{n+k+1}^{\dagger}(i)A_{n+k+1}(i), k = 1, \ldots, n - 1, \tag{3.27}
\]

\[
H_{\beta}^{(r)} = r - \sum_{i=1}^{r} A_{1}(i)A_{1}^{\dagger}(i) - \sum_{i=1}^{r} A_{n+1}(i)A_{n+1}^{\dagger}(i) \tag{3.28}
\]

\[
= -r - H_{1}^{(r)} - H_{n+1}^{(r)}. \tag{3.29}
\]
Proposition 3.20. The above elements satisfy the Serre relations for $su(n,n)$.  

Proof: As in the proof of the case $r = 1$, this follows from the Weyl–Serre Equations. \hfill \square

Notice that the center in $\mathfrak{k}C$ in this version is generated by

$$
\Omega^{(r)} = -nr - \sum_{k=1}^{2n} \sum_{i=1}^{r} A_k^\dagger(i)A_k(i).
$$

(3.30)

Definition 3.21.

$$
\Xi^{(r)} = \sum_{k=1}^{n} A_k^\dagger(i)A_k(i) - A_{n+k}^\dagger(i)A_k(i).
$$

(3.31)

One sees easily

Proposition 3.22. The element $\Xi^{(r)}$ commutes with all the elements in Definition 3.19.

Corollary 3.23. The elements above define a homomorphism

$$
\psi^{(r)} : \mathcal{U}(su(n,n)C) \to \mathcal{H}_{2nr}.
$$

(3.32)

We will occasionally extend this map to $\mathcal{U}(u(n,n)C)$ by including $\Xi^{(r)}$, and we will also use the name $\psi^{(r)}$ in these cases.

Definition 3.24. The representation

$$
\mathcal{R}^{\text{harm}}_r = \pi_{2nr}^{suN} \circ \psi^{(r)}
$$

is the $(r\text{th})$ Harmonic Representation of $\mathcal{U}(u(n,n)C)$ in $\mathcal{F}_{2nr}$.

Set

\[
X^{(k)} = \begin{pmatrix}
A_1^{(1)} & A_1^{(2)} & \cdots & A_1^{(k)} \\
A_2^{(1)} & A_2^{(2)} & \cdots & A_2^{(k)} \\
\vdots & \vdots & \ddots & \vdots \\
A_n^{(1)} & A_n^{(2)} & \cdots & A_n^{(k)}
\end{pmatrix}
\quad \text{and} \quad
Y^{(k)} = \begin{pmatrix}
A_{n+1}^{(1)} & A_{n+1}^{(2)} & \cdots & A_{n+1}^{(k)} \\
A_{n+2}^{(1)} & A_{n+2}^{(2)} & \cdots & A_{n+2}^{(k)} \\
\vdots & \vdots & \ddots & \vdots \\
A_{2n}^{(1)} & A_{2n}^{(2)} & \cdots & A_{2n}^{(k)}
\end{pmatrix}.
\]

(3.33)

Set

$$
\mathbb{W}^{(k)} = (X^{(k)})^T(Y^{(k)}).
$$

(3.34)

Analogously to Lemma 3.10, we have:

Lemma 3.25. For $k, \ell < n$,

$$
W_{k+1,\ell}^{(r)} = \text{ad}(F^r_{\mu_k})W_{k,\ell}^{(r)} \quad \text{and} \quad W_{k,\ell+1}^{(r)} = \text{ad}(F^r_{\nu_\ell})W_{k,\ell}^{(1)}.
$$

Let $\mathcal{I}_{k \times k}$ denote the ideal in $\mathcal{P}$ generated by all $k \times k$ minors of $\mathbb{W}$.

In complete analogy with the $2 \times 2$ case we obtain the following theorem and proposition. The result was first proved in ([27]).
Specifically, we consider variables of convenient notation which also facilitates a comparisons to Kashiwara–Vergne (26).

We will also add a subscript $L$ to extend to homomorphisms $U(u^\mathbb{C}(r)) \rightarrow \mathcal{H}_{2nr}$, respectively. We will think of the variables $x$ as a classical analogue of a Drinfeld Double. See §4.

**Proposition 3.27.** The recipes

$$
\forall i, j = 1, \ldots, r : E_{ij} \xrightarrow{\Gamma_i^{(r)}} \sum_{a=1}^{n} A_a^\dagger(i) A_a(j),
$$

$$
\forall i, j = 1, \ldots, r : E_{ij} \xrightarrow{\Gamma_2^{(r)}} \sum_{b=1}^{n} A_{n+b}(i) A_{n+b}(j), \text{ and}
$$

$$
\forall i, j = 1, \ldots, r : E_{ij} \xrightarrow{\Gamma_3^{(r)}} \sum_{a=1}^{n} A_a^\dagger(i) A_a(j) - \sum_{b=1}^{n} A_{n+b}(i) A_{n+b}(j)
$$

extend to homomorphisms $U(u^\mathbb{C}(r)) \rightarrow \mathcal{H}_{2nr}$, $i = 1, 2, 3$.

**Proof:** This again follows directly from the Serre-Weyl equations. The first two homomorphisms of course take values in two subalgebras isomorphic to $\mathcal{H}_{nr}$, and these subalgebras have trivial intersection. The third homomorphism can be seen as a classical analogue of a Drin’feld Double. See §4.

**Proposition 3.28.** An element $h \in \mathcal{H}_{2nr}$ commutes with $\psi^{(r)}(U(u(n, n)^\mathbb{C}))$ if and only $h \in \Gamma_3^{(r)}(U(u(r)^\mathbb{C}))$.

We shall prove this result in the next section when more notation is available.

4. **The Kashiwara–Vergne list of unitary representations**

4.1. **The $U(n) \times U(n) \times U(r) \times U(r)$ module $\mathcal{F}_{2nr}$.** We first introduce some convenient notation which also facilitates a comparisons to Kashiwara–Vergne (26).

Specifically, we consider variables

$$
\forall i = 1, \ldots, n; \forall j = 1, \ldots, r : x_{ij} = A_i^\dagger(j) \text{ and } y_{ij} = A_{n+i}(j).
$$

We consider the space $\mathcal{P}_{2nr}$ of polynomials in these commuting variables. Let $\mathcal{P}_{nr}^x$ and $\mathcal{P}_{nr}^y$ denote the spaces of polynomials in $x$ and $y$, respectively, so that $\mathcal{P}_{2nr} = \mathcal{P}_{nr}^x \cdot \mathcal{P}_{nr}^y$. Evidently there is a monomial basis

$$
x^a y^b = \prod_{(i,k)=(1,1)}^{(n,r)} x_{i,k}^{a_{i,k}} \prod_{(i,k)=(1,1)}^{(n,r)} y_{i,j}^{b_{i,j}},
$$

of $\mathcal{P}_{2nr}$, where $a, b$ are elements in $\mathbb{N}_{0}^{nr}$.

We will think of the variables $x_{ij}$ and $y_{ij}$ as the entries of $n \times r$ matrices $x$ and $y$, respectively.

There is an action of $Gl(n, \mathbb{C}) \times Gl(n, \mathbb{C})$ from the left;

$$
\forall a, b \in Gl(n, \mathbb{C}) \times Gl(n, \mathbb{C}) : ((a, b) \ast p)(x, y) = p(a^T \cdot x, b^T \cdot y).
$$

We will equip the groups $GL(n, \mathbb{C})$ with a superscript $X$ or $Y$ according to which type of variables they act on. We will also add a subscript $L$ for this left action.
Similarly, there is an action on the Lie algebra level. Later there will be a right action of a matrix group which will be labeled with a subscript $R$, and appropriate superscripts. The Lie algebras get labels $X, Y, L,$ and $R$, similarly. We maintain the notation $\mathcal{P}_{2nr}$, now as a $gl_X^L(n, \mathbb{C}) \times gl_Y^L(n, \mathbb{C})$ module as described above.

It is clear that there is a vector space isomorphism

$$\mathcal{I}_{2nr} : \mathcal{P}_{2nr} \rightarrow \mathcal{F}_{2nr}. \quad (4.4)$$

We have that $\mathcal{F}_{2nr}$ is a $\mathcal{U}(u(n, n)^{\mathbb{C}})$ module via $\psi^{(r)} \circ \pi_{2nr}^{S_{2n}}$, and thus $\mathcal{P}_{2nr}$ becomes a $u(n, n)^{\mathbb{C}}$ module. We denote this module by $\mathcal{P}_{2nr}^F$. An easy computation gives that as a $gl_X^R(n, \mathbb{C}) \times gl_Y^R(n, \mathbb{C})$ module, it is twisted in comparison to $\mathcal{P}_{2nr}$:

$$\mathcal{P}_{2nr}^F = \mathcal{P}_{2nr} \otimes \mathbb{C} C^r_2, \quad (4.5)$$

where $C^r_2$ is the 1-dimensional module in which each $H_k$ acts as $\frac{1}{2}r$. Notice in this connection that we work with an “abstract” realization of $u(n, n)$ as $\infty \times \infty$ matrices. In our present setting, there is no underlying faithful finite dimensional representation.

One easily obtains the following expressions for the generators when expressed on $\mathcal{P}_{2nr}^F$:

**Lemma 4.1.**

$$e^{(r)}_\beta = - \sum_{i=1}^{r} \frac{\partial}{\partial x_{1,i}} \frac{\partial}{\partial y_{1,i}}, \quad (4.6)$$

$$e^{(r)}_j = \sum_{i=1}^{r} x_{j,i} \frac{\partial}{\partial x_{j+1,i}} \quad (j = 1, \ldots, n - 1), \quad (4.7)$$

$$e^{(r)}_j = \sum_{i=1}^{r} y_{j,i} \frac{\partial}{\partial y_{j+1,i}} \quad (j = n - 1, \ldots, 2n - 1), \quad (4.8)$$

$$f^{(r)}_\beta = \sum_{i=1}^{r} x_{1,i} y_{1,i}, \quad (4.9)$$

$$f^{(r)}_j = \sum_{i=1}^{r} x_{j+1,i} \frac{\partial}{\partial x_{j,i}} \quad (j = 1, \ldots, n - 1), \quad (4.10)$$

$$f^{(r)}_j = \sum_{i=1}^{r} y_{j+1,i} \frac{\partial}{\partial y_{j,i}} \quad (j = n + 1, \ldots, 2n - 1). \quad (4.11)$$
\begin{align*}
H_k^{(r)} &= \frac{r}{2} + \sum_{i=1}^{r} x_{k,i} \frac{\partial}{\partial x_{k,i}} \quad (k = 1, \ldots, n), \\
H_{k+n}^{(r)} &= \frac{r}{2} + \sum_{i=1}^{r} y_{k,i} \frac{\partial}{\partial y_{k,i}} \quad (k = 1, \ldots, n), \\
H_\beta^{(r)} &= -r - \sum_{i=1}^{r} x_{1,i} \frac{\partial}{\partial x_{1,i}} - \sum_{i=1}^{r} y_{1,i} \frac{\partial}{\partial y_{1,i}}, \\
\Omega_c^{(r)} &= -nr - \sum_{k=1}^{n} \sum_{i=1}^{r} x_{k,i} \frac{\partial}{\partial x_{k,i}} - \sum_{k=1}^{n} \sum_{i=1}^{r} y_{k,i} \frac{\partial}{\partial y_{k,i}}, \\
\Xi^{(r)} &= \sum_{k=1}^{n} \sum_{i=1}^{r} x_{k,i} \frac{\partial}{\partial x_{k,i}} - \sum_{k=1}^{n} \sum_{i=1}^{r} y_{k,i} \frac{\partial}{\partial y_{k,i}},
\end{align*}

There is an additional group acting on \( P_{2nr} \):

\[ \forall p \in P_{2nr}, \forall u \in U(r) : (p \ast u)(x, y) = p(x \cdot u^{-1}, y \cdot u^T). \quad (4.17) \]

We may even consider an action of \( \text{Gl}_X^X(r, \mathbb{C}) \times \text{Gl}_Y^Y(r, \mathbb{C}) \):

\[ \forall p \in P_{2nr}, \forall c, d \in \text{Gl}_X^X(r, \mathbb{C}) \times \text{Gl}_Y^Y(r, \mathbb{C}) : (p \ast (c, d))(x, y) = p(x \cdot c^{-1}, y \cdot d^T). \quad (4.18) \]

We have labeled the groups by \( R \) for this right action. The previous action of \( U(r) \) is then the restriction to the diagonal of this, more general, action. Corresponding to this, we let

\[ \text{Gl}_R^D(r, \mathbb{C}) = \{(u, u) \in \text{Gl}_X^X(r, \mathbb{C}) \times \text{Gl}_Y^Y(r, \mathbb{C}) | u \in \text{Gl}(r, \mathbb{C})\} \quad (4.19) \]

denote the diagonal subgroup of the product.

These actions can be carried over to \( \mathcal{F}_{2nr} \) by letting the two copies of \( U(r) \) act trivially (i.e. as 1) on \( v_{2nr} \).

This action clearly commutes with the action of \( \text{Gl}_L^X(n, \mathbb{C}) \times \text{Gl}_L^Y(n, \mathbb{C}) \) from the left.

The action of the diagonal sub-algebra is given as follows (c.f. the third formula in (3.35))

\[ \forall i, j = 1, \ldots, r : p \ast O_{ij} := p \ast (E_{i,j} - E_{j,i}) = \left(-\sum_{k=1}^{n} x_{k,i} \frac{\partial}{\partial x_{k,j}} + \sum_{k=1}^{n} y_{k,j} \frac{\partial}{\partial y_{k,i}}\right) p. \quad (4.20) \]

**Proof of Proposition 3.28**: It follows easily from the relations (3.8-3.10) that

\[ \Gamma_3^{(r)}(\mathcal{U}(u(r)^\mathbb{C})) \subseteq \left(\psi^{(r)}(\mathcal{U}(u(n,n)^\mathbb{C}))\right)'. \quad (4.21) \]

(The right hand side is the commutant in \( \mathcal{H}_{2nr} \)). Let then \( h \in \left(\psi^{(r)}(\mathcal{U}(u(n,n)^\mathbb{C}))\right)' \).

We may analyze \( h \) through its action \( \pi^{SeN}(h) \) in \( \mathcal{F}_{2nr} \), or directly.
\[ h = \sum_{i,j,k,\ell} p_i^{(1)} p_j^{(2)} p_k^{(3)} p_\ell^{(4)}, \quad (4.22) \]

where \( p_i^{(1)} \) is a polynomial on the variables \( A_i^a(b), 1 \leq a \leq n, 1 \leq b \leq r, \) and \( p_j^{(2)}, p_k^{(3)}, p_\ell^{(4)} \) are polynomials on the variables \( A_a(b), A_{n+a}(b), 1 \leq a \leq n, 1 \leq b \leq r, \) and \( A_{n+a}(b), 1 \leq a \leq n, 1 \leq b \leq r, \) respectively. Consider

\[ \sum_{i,j} p_i^{(1)} p_j^{(2)} p_k^{(3)} p_\ell^{(4)}, \quad (4.23) \]

\( p_k^{(3)} p_\ell^{(4)} \) fixed, but arbitrary. This must be invariant under the \( u(n) \) defined from the elements \( F_{\mu_k}^{(r)}, E_{\mu_k}^{(r)}, k = 1, \ldots, n - 1. \) The elements \( p_i^{(1)} \) transform under \( u(n) \) according to a sum of irreducible representations, and so do elements \( p_j^{(2)}. \) To pick up the trivial representation, we need the representations to be pairwise duals of each other. It follows that the degree of homogeneity of \( p^{(1)} \) must be the same as that of \( p^{(2)}, \) though of course in different variables, Indeed, taken together they are products of first order differential operators. These are left invariant. This means that they come from the right action. By similar reckoning for the other variables, it follows that in the representation, \( h \) can be represented by an element in \( \mathcal{U}(gl(r, \mathbb{C}) \times gl(r, \mathbb{C})) \) (acting from the right). Let \( \mathcal{U}_D(r) \) be the subalgebra of this algebra generated by the elements \( (C, -CT) \) and let \( \mathcal{U}_X(r) \) be the subalgebra generated by the elements \( (C, 0). \) Clearly,

\[ \mathcal{U}(gl(r, \mathbb{C}) \times gl(r, \mathbb{C})) = \mathcal{U}_X(r) \cdot \mathcal{U}_D(r). \quad (4.24) \]

Let

\[ \mathcal{M} = \text{Ideal} \left( \sum_{s=1}^{r} (A_i(s))(A_{n+j}(s)); \ i, j = 1, \ldots, n \right), \quad (4.25) \]

and let

\[ \mathcal{M}^\dagger = \text{Ideal} \left( \sum_{s=1}^{r} (A_i(s))^\dagger(A_{n+j}(s))^\dagger; \ i, j = 1, \ldots, n \right). \quad (4.26) \]

The generators of these are easily seen to belong to \( (\psi^{(r)}(\mathcal{U}(u(n, n)^\mathbb{C}))) \) and hence \( h \) must commute with both ideals.

We have already established (though left it to the reader) that \( \mathcal{U}_D(r) \) commutes with the ideals. If \( h \) does not belong to \( \mathcal{U}_D(r), \) e.g.

\[ h = \sum_i u_X^{(i)} u_D^{(i)}, \quad (4.27) \]

with at least one \( u_X^{(i)} \) different from a complex constant, then it follows that there must be a non-trivial element of \( \mathcal{U}_X(r) \) that commutes with both ideals. But observe that the elements \( A_{n+i}(j) \) and \( A_{n+i}(\ell) \) are invariant placeholders in the commutators. It follows that there must be a non trivial element in \( \mathcal{U}_X(r) \) that commutes
with all elements in $\mathcal{H}_{nr}$ (the first $r$ places) and hence even with $\mathcal{H}_{2nr}$. It is well known that the center of the Weyl algebra is $\mathbb{C}$, so this is a contradiction. □

We first consider the spaces $\mathcal{P}^X_{nr}$ and $\mathcal{P}^Y_{nr}$ separately. The respective left-right actions correspond to (4.3) and (4.17).

**Definition 4.2.** $\forall j = 1, \ldots, r$:
\[
\triangle_j(x) = \det \begin{pmatrix} x_{1,1} & \cdots & x_{1,j} \\ x_{j,1} & \cdots & x_{j,j} \end{pmatrix} \quad \text{and} \quad \tilde{\triangle}_j(y) = \det \begin{pmatrix} y_{1,k-j+1} & \cdots & y_{1,k} \\ y_{j,k-j+1} & \cdots & y_{j,k} \end{pmatrix}.
\]
(4.28)

The following is a well-known result of De Concini, Eisenbud, and Procesi ([5]):

**Proposition 4.3 ([5]).** Let $c_1, \ldots, c_i, \cdots, c_m$, where $m = \min\{n, r\}$, be non-negative integers. Then
\[
\triangle(x)^c = \prod_{k=1}^m \triangle_k^c(x)
\]
(4.29)
is a highest weight vector for the combined action of $GL^X_L(n, \mathbb{C}) \times GL^X_R(r, \mathbb{C})$ on $\mathcal{P}^X_{nr}$, and any highest weight vector is of this form. There are no multiplicities. The corresponding highest weight for $GL^X_R(r, \mathbb{C})$, given as a linear functional on the diagonal of $gl^X_R(r, \mathbb{C})$, is
\[
\Lambda_{gl^X_R(r)} = (c_1 + \cdots + c_i, c_2 + \cdots + c_m, \ldots, c_m, 0, \ldots, 0),
\]
and, analogously,
\[
\Lambda_{gl^X_L(n)} = (c_1 + \cdots + c_i, c_2 + \cdots + c_m, \ldots, c_m, 0, \ldots, 0).
\]
(4.30) (4.31)
(The pair $(\Lambda_{gl^X_L(n)}, \Lambda_{gl^X_R(r)})$ is often called a “double tableau”.) Let $V^X_{LR;m}$ denote the corresponding representation.

Similarly, let $d_1, \ldots, d_m$ be non-negative integers. Then
\[
\tilde{\triangle}(y)^d = \prod_{\ell=1}^m \tilde{\triangle}_\ell^d(y)
\]
(4.32)
is a highest weight vector for the combined action of $GL^Y_L(n, \mathbb{C}) \times GL^Y_R(r, \mathbb{C})$ on $\mathcal{P}^Y_{nr}$. Again, this is the most general form and there are no multiplicities. The highest weight for the $GL^Y_R(r, \mathbb{C})$, given as a linear functional on the diagonal of $gl^Y_R(r, \mathbb{C})$, is
\[
\Lambda_{gl^Y_R(r)} = (0, \ldots, 0, -d_m, \ldots, -d_m - d_{m-1} \cdots - d_1).
\]
(4.33)
Here we get
\[
\Lambda_{gl}(n) = (d_1 + d_2 + \cdots + d_m, d_2 + \cdots + d_m, 0, \ldots, 0),
\]
and we let \( V_{LR}^n \) denote the corresponding representation.

If \( N_m \) denotes the set of such \( m \) tuples, then
\[
\mathcal{P}_{nr}^X = \bigoplus_{a \in N_m} V_{LR}^X.
\]
Likewise,
\[
\mathcal{P}_{nr}^Y = \bigoplus_{b \in N_m} V_{LT}^Y.
\]

We then have the following easy corollary, where we still use the restriction of the action \( (4.17) \) to the relevant spaces:

**Corollary 4.4.** If a \( GL^X_L(n, \mathbb{C}) \) highest weight vector \( p \in \mathcal{P}_{nr}^X \) of highest weight \( a = (a_1, \cdots, a_m, 0, \cdots, 0) \) is given, then there exists \( u \in U^+(gl^{X}_R(r, \mathbb{C})) \) such that
\[
p \ast u = \Delta(x)^a.
\]
If a \( GL^Y_L(n, \mathbb{C}) \) highest weight vector \( \hat{p} \in \mathcal{P}_{nr}^Y \) of highest weight \( (b_1, \cdots, b_m, 0, \cdots, 0) \) is given, then there exists \( u \in U^+(gl^{Y}_R(r, \mathbb{C})) \) such that
\[
\hat{p} \ast u = \tilde{\Delta}(y)^b.
\]

### 4.2. Highest weights in two different bases.

Set \( e = (1,1,\cdots,1) \). Any highest weight vector \( p_a^X p_b^Y \) in \( \mathcal{P}_{nr} \) of highest weight \((a,b)\) defines a highest weight vector \( p_a^X p_b^Y \cdot v_{2nr} \) for \( u(n) \times u(n) \) in \( \mathcal{F}_{2nr} \) whose weight \( \Lambda_{a,b} = (a + \frac{r}{2}e, b + \frac{r}{2}e) \), we want to write according to our other parametrization;
\[
\Lambda_{a,b} = ((i_1, \cdots, i_{n-1}, 0), (j_1, \cdots, j_{n-1}, 0), \lambda_\beta, \zeta),
\]
where \((i_1, \cdots, i_{n-1}, 0)\) and \((j_1, \cdots, j_{n-1}, 0)\) determine the same weights of \( \mathfrak{f}^c_L \) and \( \mathfrak{f}^c_R \), respectively, as does \((a, b)\), and where
\[
H^{(r)}_{\beta} p_a^X p_b^Y \cdot v_{2nr} = \lambda_\beta \cdot p_a^X p_b^Y \cdot v_{2nr} \quad \text{and} \quad \Xi^{(r)} p_a^X p_b^Y \cdot v_{2nr} = \zeta \cdot p_a^X p_b^Y \cdot v_{2nr}.
\]
Notice that e.g. $x_{11} \frac{\partial}{\partial x_{11}}$ applied to an element as in (4.29) gives $(c_1 + c_2 + \cdots + c_m)$ times the element, it follows that

\begin{align*}
i_k &= a_k - a_n, \quad k = 1, \ldots, n - 1, \\
j_k &= b_k - b_n, \quad k = 1, \ldots, n - 1,
\end{align*}

(4.41) (4.42)

\[\lambda_\beta = -r - a_1 - b_1 = -r - i_1 - j_1 - (a_n + b_n), \quad \text{and} \]

\[\zeta = \sum_i a_i - \sum_j b_j = n(a_n - b_n) + \sum_k (i_k - j_k). \tag{4.44}\]

Notice that if we set

\[\Omega^{(r)}_{\mathbb{C}} p_a p_b^* \cdot \nu_{2nr} = \lambda_c \cdot p_a p_b^* \cdot \nu_{2nr}, \tag{4.45}\]

then $\lambda_c = -nr - \sum_i a_i - \sum_j b_j$. A small computation reveals that the two parameters $\lambda_\beta, \lambda_c$ are connected by the equation

\[\lambda_\beta = -i_1 - j_1 + \frac{1}{n}(\lambda_c + \sum_k (i_k + j_k)). \tag{4.46}\]

We further notice that

\[\lambda_\beta \leq -r - i_1 - j_1. \tag{4.47}\]

Hence, $b := -\lambda_\beta - r - i_1 - j_1 \geq 0$, It follows by linear algebra that to a given set $((i_1, \cdots, i_{n-1}, 0), (j_1, \cdots, j_{n-1}, 0), \lambda_\beta)$ with $\lambda_\beta$ as in (4.43), the following set of $(a, b)$ correspond to this:

\[
a = \begin{pmatrix}
i_1 + a \\
n_2 + a \\
\vdots \\
i_{n-1} + a \\
a
\end{pmatrix} \quad b = \begin{pmatrix}
j_1 + b - a \\
n_2 + b - a \\
\vdots \\
j_{n-1} + b - a \\
b - a
\end{pmatrix} \quad 0 \leq a \leq b. \tag{4.48}\]

The value $\zeta(a)$ corresponding to a solution determined by the parameter $a$ is

\[\zeta(a) = n(2a - b) + \sum_k i_k - \sum_k j_k. \tag{4.49}\]

The value $\zeta$ above is important later when we discuss multiplicities, but for the next several sections it will be omitted, since we here discuss $\mathcal{U}(su(n, n)^\mathbb{C})$ modules in which $\Xi$ is a constant, $\zeta$, times the identity.

4.3. Top pluri-harmonic elements. Recall (see e.g. [37, §1.5]) that unitarity on a highest weight module $M$ for $su(n, n)^\mathbb{C}$ is defined in terms of the Hermitian form $\langle \cdot, \cdot \rangle$ uniquely given by the anti-linear anti-involution $\omega$,

\[
\omega(E_\alpha) = F_\alpha \text{ if } \alpha \text{ is compact, and} \]

\[
\omega(E_\beta) = -F_\beta. \tag{4.51}\]

Then, $su(n, n)$ is the $-1$ eigenspace of $\omega$ in $su(n, n)^\mathbb{C}$.

The defining property is

\[
\forall v_1, v_2 \in M, \forall X \in su(n, n)^\mathbb{C} : \langle Xv_2, v_1 \rangle = \langle v_2, \omega(X)v_1 \rangle. \tag{4.52}\]
It is easy to see that
\[ \forall X \in su(n, n)^{\mathbb{C}} : (\mathcal{R}_r^{\text{harm}}(X))^* = \mathcal{R}_r^{\text{harm}}(\omega(X)). \] (4.53)

The representation \( \mathcal{R}_r^{\text{harm}} \) of \( su(n, n)^{\mathbb{C}} \) in the (pre-)Hilbert space \( \mathcal{F}_{2nr} \) is obviously unitarizable.

If we take the cyclic span of the vector \( v_{2nr} \) we get in particular:

**Proposition 4.5.** In the space
\[ \mathcal{H}_{(0,0,-1)} = \text{Span}_{\mathbb{C}} \{ W_{i_1,j_1}^{(1)} W_{i_2,j_2}^{(1)} \cdots W_{i_r,j_r}^{(1)} \cdot v_0 \mid r \geq 0, i_1, \ldots, j_r \in \{1, \ldots, n\} \} \] (4.54)
there is a unitarizable representation of \( su(n, n) \) of highest weight \( (0,0,-1) \).

We now wish to decompose \( \mathcal{F}_{2nr} \) completely under \( \mathcal{R}_r^{\text{harm}} \). Clearly, we then need to look for vectors \( v_\Lambda \in \mathcal{F}_{2nr} \) that are weight vectors for the Cartan subalgebra of weight \( \Lambda \) and satisfy

\[
E_{\beta}^{(r)} v_\Lambda = 0, \quad E_{\mu_k}^{(r)} v_\Lambda = 0, \quad \text{and} \quad E_{\nu_k}^{(r)} v_\Lambda = 0, \]

or, equivalently, weight vectors \( v_\Lambda \) of weight \( \Lambda \) that satisfy

\[
\sum_{s=1}^{r} (A_1^{(s)}) (A_{n+1}^{(s)}) v_\Lambda = 0, \quad \text{(4.58)}
\]

\[
\sum_{s=1}^{r} (A_{k+1}^{(s)}) (A_k^{(s)})^\dagger v_\Lambda = 0, \quad \text{and} \quad \text{(4.59)}
\]

\[
\sum_{s=1}^{r} (A_{n+\ell}^{(s)})^\dagger (A_{n+\ell+1}^{(s)}) v_\Lambda = 0. \quad \text{(4.60)}
\]

**Definition 4.6.** We call a non-zero vector \( v_\Lambda \) **top pluri-harmonic** of weight \( \Lambda \) if it satisfies (4.55-4.57) and is a weight vector of \( su(n, n) \) of weight \( \Lambda \). Equivalently, if \( \mathcal{U}^+ v_\Lambda = 0 \). If it furthermore is an eigenvector of \( \Xi^{(r)} \) of eigenvalue \( \zeta \), we say that it has weight \( (\Lambda, \zeta) \).

As previously, \( v_{2nr} \) denotes the vacuum vector in \( \mathcal{F}_{2nr} \). Of course, it is top pluri-harmonic.

The origin of this terminology can be found in ([26]).

It is clear that any top pluri-harmonic vector will determine an invariant submodule. Furthermore, a maximal set of orthogonal top pluri-harmonic vectors will yield the full decomposition.

Let us first look at the case \( r = 1 \), i.e. \( \mathcal{F}_{2n} \): It is easy to see that this space transforms under \( u(n) \times u(n) \) as sums of symmetrized tensor products of the defining representation and that one indeed has:
Proposition 4.7. As a $u(n) \times u(n)$ module,
\[ \mathcal{F}_{2n} = \oplus_{N,S \in \mathbb{N}_0} V_{N,S}, \quad (4.61) \]
where $V_{N,S}$ is the irreducible module with highest weight vector $(A_1^\dagger)^N(A_{n+1}^\dagger)^S v_{2n}$.

The top pluri-harmonic elements are exactly the elements
\[ (A_1^\dagger)^N v_{2n} \quad \text{and} \quad (A_{n+1}^\dagger)^S v_{2n}; \quad N, S \in \mathbb{N}_0. \quad (4.62) \]

We set
\[ V_N^L = V_{((N,0,\ldots,0),0,-1-N)} \quad \text{and} \quad V_S^R = V_{(0,(S,0,\ldots,0),-1-S)} \quad (4.63) \]
for the corresponding $\mathfrak{k}^C$ modules, written in accordance with (4.39) but ignoring the value $\zeta$.

Let $\hat{M}(V_N^L)$ and $\hat{M}(V_S^R)$ denote the unitary representations of $su(n,n)$ in $\mathcal{F}_{2n}$ generated by the above top pluri-harmonic elements.

The $su(n,n)$ highest weights are, respectively, written according to (4.39) but ignoring the value $\zeta$,
\[ V_N^L = V_{((N,0,\ldots,0),0,-1-N)} \quad \text{and} \quad V_S^R = V_{(0,(S,0,\ldots,0),-1-S)}. \quad (4.64) \]

Then, as a $su(n,n)$ module,
\[ \mathcal{F}_{2n} = \bigoplus_{N=0}^\infty \hat{M}(V_N^L) \bigoplus \bigoplus_{S=1}^\infty \hat{M}(V_S^R). \quad (4.65) \]

These representations are irreducible. They are indeed the irreducible quotients of the corresponding generalized Verma modules $M(V_N^L)$ and $M(V_S^R)$, respectively.

The $\mathfrak{k}^C$-types are as follows:
\[ \hat{M}(V_N^L) : \quad \mathfrak{k}^C\text{-types: } \bigoplus_{i \in \mathbb{N}_0} V_{((N+i,0,\ldots),(i,0,\ldots),-N-2i-1)}, \quad \text{and} \quad (4.66) \]
\[ \hat{M}(V_S^R) : \quad \mathfrak{k}^C\text{-types: } \bigoplus_{j \in \mathbb{N}_0} V_{((j,0,\ldots),(S+j,0,\ldots),-S-2j-1)}, \quad (4.67) \]
corresponding to the highest weight vectors $(A_1^\dagger)^{N+i}(A_{n+1}^\dagger)^i v_{2n}$ and $(A_1^\dagger)^j(A_{n+1}^\dagger)^{S+j} v_{2n}$, respectively.

Proof: The first statement about the $\mathfrak{k}^C$-types is obvious, and so is the statement about the highest weight vectors. The irreducibility and the content of $\mathfrak{k}^C$-types of the individual representations go hand in hand: The spectrum of $\mathfrak{k}^C$-types is in a very obvious way 1-dimensional. If some $\hat{M}(V_N^L)$ or $\hat{M}(V_S^R)$ contained fewer $\mathfrak{k}^C$-types than the stated (i.e. that some types were “missing”), there would be a gap in the spectrum which would force the unitarizable $su(n,n)$ representation to be finite-dimensional. The only such is the trivial representation, and this is clearly not one of ours since the vacuum vector is not annihilated by $F_\beta$. \qed

Remark 4.8. We here encounter for the first time the notion of “missing” $\mathfrak{k}^C$-types. We return to these notions below and their relation to homomorphisms between Verma modules. In this context another proof of the above will be furnished as a special case of the general analysis.

The representations above are generalizations of the so-called ladder representations (see e.g. [31]). Even though they contain all the mentioned $\mathfrak{k}^C$-types, they have
very thin sets of $\frak{t}^C$-types and in a very specific sense, many other $\frak{t}^C$-types are “missing” (see below). They are the spaces of the mass 0, spin $N/2$, or spin $S/2$ particles, though it might be better to talk about helicity instead of spin.

More generally, in $\mathcal{F}_{2nr}$ there are some obvious top pluri-harmonic vectors: Let us denote by $\mathcal{P}^{(r)}_u$ the span of vectors of the form

$$p_u((A_1(1)\dagger, \ldots, (A_n(r)\dagger)v_{2nr},$$

(4.68)

and, likewise, by $\mathcal{P}^{(r)}_d$ the span of vectors of the form

$$p_d((A_{n+1}(1)\dagger, \ldots, (A_{2n}(r)\dagger)v_{2nr}.$$  

(4.69)

Both spaces are clearly invariant under the action of $\frak{t}^C$, an action that also preserves degrees.

$\mathcal{P}^{(r)}_u$ has a trivial action of $\frak{t}^C_R$ and decomposes under $\frak{t}^C_L$ into the $r$th fold tensor products of the symmetric tensor representations $(a, 0, \ldots)$, $a \in \mathbb{N}$. For $r < n$, any highest weight representation of the form

$$((a_1, \ldots, a_r, 0, \ldots), 0, -a_1 - r)$$

(4.70)

is obtained. For $r \geq n$ any highest weight representation of the form

$$((a_1, \ldots, a_{n-1}, 0), 0, -a_1 - \tilde{r}), \tilde{r} = r, r + 1, r + 2, \ldots$$

(4.71)

is obtained.

Similarly, $\mathcal{P}^{(r)}_d$ has a trivial action of $\frak{t}^C_R$ and decomposes under $\frak{t}^C_L$ into the $r$th fold tensor products of the symmetric tensor representations $(b, 0, \ldots)$, $b \in \mathbb{N}$. For $r < n$, any highest weight representation of the form

$$(0, (b_1, \ldots, b_r, 0, \ldots), -b_1 - r)$$

(4.72)

is obtained. For $r \geq n$ any highest weight representation of the form

$$(0, (b_1, \ldots, b_{n-1}, 0), -b_1 - \tilde{r}), \tilde{r} = r, r + 1, r + 2, \ldots$$

(4.73)

is obtained.

**Lemma 4.9.** Let $p_u v_{2nr}$ be a highest weight vector in $\mathcal{P}^{(r)}_u v_{2nr}$ of highest weight as mentioned right above. Then it is top pluri-harmonic.

Likewise, Let $p_d v_{2nr}$ be a highest weight vector in $\mathcal{P}^{(r)}_d v_{2nr}$ of highest weight as mentioned right above. Then it is top pluri-harmonic.

**Proof.** We need only examine the operators (4.58). Since the summands contain both $A_1(s)$ and $A_{n+1}(s)$, the stated vectors will be annihilated. \(\square\)

Another important observation, which follows from the above, or directly from (5), is

**Proposition 4.10.** If $r < n$, the most general $\frak{t}^C$-type in $\mathcal{F}_{2nr}$ is of the form

$$V_{(a_1, \ldots, a_r, 0, \ldots), (b_1, \ldots, b_r, 0, \ldots), -a_1 - b_1 - r}.$$  

(4.74)
If $r \geq n$, the most general $\mathfrak{v}^\mathbb{C}$-type in $\mathcal{F}_{2nr}$ is of the form

$$V(a_1, \ldots, a_{n-1}, 0, b_1, \ldots, b_{n-1}, 0, -a_1 - b_1 - r), \text{ with } a_{n-1}, b_{n-1} \geq 0, \text{ and } \bar{r} = r, r + 1, r + 2, \ldots$$

(4.75)

The multiplicities of these types have their origin in the $u(r)$ module structures:

If $r < n$ the multiplicity of $V(a_1, \ldots, a_r, 0, \ldots, b_1, \ldots, b_r, 0, \ldots)$ is given as the product of the dimensions of the irreducible representations of $u(r)$ of highest weights $(a_1, \ldots, a_r)$ and $(b_1, \ldots, b_r)$, respectively.

If $r \geq n$ the multiplicity of the $\mathfrak{v}^\mathbb{C}$-type $V((n_1, \ldots, n_{n-1}, 0), (m_1, \ldots, m_{n-1}, 0, \ldots), \lambda_\beta)$ in $\mathcal{F}_{2nr}$ is determined as follows: Set $\Gamma = -\lambda_\beta - r - n_1 - m_1$. Then the multiplicity is zero unless $\Gamma$ is a non-negative integer. Set $\mathbf{e} = (1, 1, \ldots, 1)$ then then pair $\mathbf{a}, \mathbf{b}$, where

$$a = (a_1, a_2, \ldots, a_n) = (n_1, \ldots, n_{n-1}, 0) + a_n \cdot \mathbf{e} \quad (4.76)$$

$$b = (b_1, b_2, \ldots, b_n) = (m_1, \ldots, m_{n-1}, 0) + n_n \cdot \mathbf{e} \quad (4.77)$$

corresponds to $V((n_1, \ldots, n_{n-1}, 0), (m_1, \ldots, m_{n-1}, 0, \ldots), \lambda_\beta)$ precisely when $a_n + b_n = \Gamma$ and $a_\beta, b_\beta \in \mathbb{N}_0$. Let $A_n$ denote the dimension of the irreducible finite-dimensional representation of $u(r)$ of highest weight $(a_1, a_2, \ldots, a_n, 0, 0, \ldots, 0)$ determined as above, and let $B_n$ denote the dimension of the irreducible finite-dimensional representation of $u(r)$ of highest weight $(b_1, b_2, \ldots, b_n, 0, 0, \ldots, 0)$ also determined as above.

The multiplicity of $\mathfrak{v}^\mathbb{C}$-type $V((n_1, \ldots, n_{n-1}, 0), (m_1, \ldots, m_{n-1}, 0, \ldots), \lambda_\beta)$ in $\mathcal{F}_{2nr}$ is then given as

$$\sum_{\substack{a_n + b_n = \Gamma \\ a_n, b_n \in \mathbb{N}_0}} A_n \cdot B_n. \quad (4.78)$$

**Corollary 4.11.** If $r < n$, $\mathcal{F}_{2nr}$ is missing all $\mathfrak{v}^\mathbb{C}$-types

$$((a_1, \ldots, a_x, 0, \ldots), (b_1, \ldots, b_y, 0, \ldots), -a_1 - b_1 - r) \text{ with } x > r \text{ or } y > r. \quad (4.79)$$

In this sense, the general case $r \in \mathbb{N}$ is similar to the case $r = 1$. However, the general case is much more complicated; there are other representations to take into account, and the group $u(r)$ becomes much more important.

### 4.4. The Littlewood-Richardson Rule.

For a statement and proof of this celebrated rule, see [22, p. 60-65].

**Lemma 4.12** (The Littlewood-Richardson Rule, very special case).

$$V(k_1, \ldots, k_r, 0, \ldots) \otimes V(a, 0, \ldots) = \bigoplus_{(j_1, j_2, \ldots, j_{r+1}, 0, \ldots) \in T} V(j_1, j_2, \ldots, j_{r+1}, 0, \ldots). \quad (4.80)$$

The set $T$ is defined as follows: $(j_1, j_2, \ldots, j_{r+1}, 0, \ldots) \in T$ if and only if it satisfies:

$$j_1 \geq k_1, \sum_{\alpha} j_\alpha = a + \sum_{\beta} i_\beta \text{ and } j_x > k_x \Rightarrow j_x \leq k_{x-1}(x = 2, \ldots, r + 1). \quad (4.81)$$
4.5. **On “missing” \(k^C\)-types.** We now, briefly, describe “missing \(k^C\)-types”:

Until further notice, we consider a general Lie algebra \(g^C\) associated to a Hermitian symmetric space and we let \(g^C = p^- \oplus k^C \oplus p^+\) be a standard decomposition ([14, p. 589]).

Recall that the Generalized Verma Module \(M(V_\tau)\) defined by a finite dimensional (irreducible) \(k^C\)-module \(V_\tau\) is

\[
M(V_\tau) = U \otimes_{U(p^+ \oplus k^C)} V_\tau,
\]

where we let \(U(p^+)\) act trivially on \(V_\tau\). The action is then from the left. The action of \(k^C\) on \(U(p^-)\) is well understood. If \(U(p^-)_d = \oplus_i V_{0,d,i}\) (4.83)

is the decomposition of the degree \(d\) elements into irreducible representations, we shall refer to the representations \(V_{0,d,i}\) as the \(d\)th order representations. Clearly, the \(k^C\)-types of \(M(V_\tau)\) are

\[
M(V_\tau) = \tau \otimes (\oplus_{d=0}^\infty \oplus_i V_{0,d,i}).
\] (4.84)

Let \(v_\tau\) be an essentially unique highest weight vector of \(M(V_\tau)\) and let \(\tilde{M}(V_\tau)\) be a quotient module of \(M(V_\tau)\) in which the image \(\tilde{v}_\tau\) of \(v_\tau\) is non-zero. We will quite generally call such modules top quotients. There is no demand of irreducibility, so a generalized Verma module itself is also considered a top quotient.

**Definition 4.13.** An irreducible representation \(\mu_0 \in \tau \otimes (\oplus_i \mu_{d,i})\) is said to be missing from \(\tilde{M}(V_\tau)\) if its multiplicity in \(\tilde{M}(V_\tau)\) is smaller than its multiplicity in \(M(V_\tau)\).

**Remark 4.14.** In this context, if there are missing \(k^C\)-types, there is also a covariant differential operator. Specifically, a missing \(k^C\)-type \(V_\tau^s\) of smallest possible degree defines a homomorphism

\[
M(V_\tau^s) \xrightarrow{\psi} M(V_\tau).
\] (4.85)

The covariant differential operator \(D_\psi\) is then the dual of this map. And vice versa. Furthermore, the null-space of this covariant differential operator is a highest weight module for the opposite algebra \(U(p^- \oplus k^C)\).

The map \(\psi\) is completely determined by the map \(\psi_0 : V_\tau^s \to M(V_\tau)\) which we can view as an element

\[
\psi_0 \in U(p^-) \otimes \text{Hom}_C(V_\tau^s, V_\tau).
\] (4.86)

By duality this directly translates into

\[
D_{\psi_0} \in U(p^+) \otimes \text{Hom}_C(V_\tau', V_\tau'),
\] (4.87)

where the elements in \(U(p^+)\) are easily read off and may be interpreted as differential operators on \(p^-\).

See ([15] and [19]) for details about this duality.
Suppose now that a first order $\mathfrak{g}_C$-type $V_{\tau_1}$ is missing from $\tilde{M}(V_{\tau})$. The assumption is equivalent to the existence of a $\mathfrak{g}_C$-type $V_{\tau_1}$ in $p^- \otimes V_{\tau}$ such that there is a non-trivial homomorphism
\[ \tilde{M}(V_{\tau_1}) \to \tilde{M}(V_{\tau}). \] (4.88)

The highest weights are related by
\[ \Lambda_{\tau_1} = \Lambda_{\tau} - \gamma, \] (4.89)
where $\gamma$ is a weight of $p^+$. 

**Lemma 4.15.** Under the above assumptions,
\[ \langle \Lambda_{\tau} + \rho, \gamma \rangle = 1. \] (4.90)

**Proof:** This follows from Harish-Chandra [13, p. 41], cf. the proof by Verma ([47]). □

The following is straightforward:

**Lemma 4.16.** The inner product on first order polynomials is given as
\[ \langle W_{-\gamma_1} v_1, W_{-\gamma_2} v_2 \rangle = -\langle v_1, Z_{\gamma_1} W_{-\gamma_2} v_2 \rangle = -\lambda \cdot \delta_{\gamma_1, \gamma_2} \langle v_1, v_2 \rangle + l.o.t. \] (4.91)

More generally, the inner product between polynomials $p_1 v_1, p_2 v_2$ of degree $d_1, d_2$, respectively, is given as
\[ (-\lambda)^{d-1} \delta_{d_1, d_2} \langle p_1, p_2 \rangle \langle v_1, v_2 \rangle + l.o.t. \] (4.92)

Recall that we have unitarity for $\lambda \in \mathbb{R}$ sufficiently small. The lemma leads directly to the last possible place of unitarity:

**Corollary 4.17.** Let $\lambda_{\text{crit}}$ be the smallest $\lambda$ for which there exists a non-compact positive root $\gamma$ such that $\Lambda - \gamma$ is a $\mathfrak{g}_C$ highest weight in $p^- \otimes V_{\Lambda}$ and such that $\langle \lambda + \rho, \gamma \rangle = 1$. Then there can be no unitarity for $\lambda > \lambda_{\text{crit}}$.

**Proof:** It follows that the inner product on any $\mathfrak{g}_C$-type in $p^- \otimes V_{\Lambda}$ is of the form $\lambda \cdot I + l.o.t.$ There is then a unique value where a such type vanishes. After that the inner product becomes negative as $\lambda$ increases. It is easy to see that a vanishing first order polynomial $p_{\gamma}$ of some $\mathfrak{g}_C$ highest weight $\Lambda_{\gamma}$ leads to a homomorphism. Specifically,
\[ \forall v \in V_{\Lambda} : \langle p_{\gamma}, W_{-\delta} v \rangle = 0, \] (4.93)
hence $Z_\delta^+ p_{\gamma} = 0$. □

Consider $\Lambda = ((i_1, \ldots, i_x, 0, \ldots), (j_1, \ldots, j_y, 0, \ldots, \lambda))$ with $x, y \leq n - 1$. (recall §4.2) It is easy to see that $\lambda_{\text{crit}}$ is attained at the first order polynomial corresponding to the representation $\Lambda_{\text{crit}} = ((i_1, \ldots, i_x, 1, 0, \ldots), (j_1, \ldots, j_y, 1, 0, \ldots, \lambda))$. The corresponding critical value then satisfies the equation
\[ \lambda_{\text{crit}} + 1 + i_1 + j_1 + x + y = 1 \text{ that is, } \lambda_{\text{crit}} = -i_1 - j_1 - x - y. \] (4.94)

**Definition 4.18.** The value $\lambda_{\text{crit}}$ is called the last possible place of unitarity.
Remark 4.19. The word “last” above has its origins in the history of the subject. One imagines that one starts at very negative values of $\lambda$ where the representations are square integrable and then proceeds towards bigger values. At very small values of $\lambda$ one has unitarity for all $\lambda$ if one passes to the universal covering group. Increasing $\lambda$ towards the last possible place one eventually passes through a finite discrete set; the so-called Wallach set ([48], [37]).

Along the same lines, we note:

Proposition 4.20. If a highest weight module $\tilde{M}(V_\tau)$ is unitarizable, then it is irreducible.

Proof: If not, there will be an element $p$ of weight different from $v_\tau$ which is annihilated by all $Z^+$. The norm of this element will then be zero, hence $p = 0$. □

4.6. The irreducible representations occurring in the $\mathcal{U}(u(n,n)\mathbb{C})$ module $\mathcal{F}_{2nr}$. We first determine the irreducible summands. Later, we will determine the multiplicities. It turns out to be convenient to extend all $\mathcal{U}(su(n,n)\mathbb{C})$ modules to $\mathcal{U}(u(n,n)\mathbb{C})$ modules by including, from Definition 3.21, the central element $\Xi^{(r)}$. Up to this point it has been irrelevant and hence dormant. In all representations we consider, it will act by multiplication by some scalar $\zeta$.

We will denote specific ones by e.g. $\tilde{M}((i_1, \cdots , i_x, 0, \cdots), (j_1, \cdots , j_y, 0, \cdots), \lambda, \zeta)$. The value of $\zeta$ will always be given in terms of data from the entering representations. We will also use the notation $M_{(\Lambda, \zeta)}$ where $(\Lambda, \zeta) = ((i_1, \cdots , i_n), (j_1, \cdots , j_n), \lambda, \zeta)$ with $\lambda$ as on p. 5, and with $\zeta \cdot 1$ the action of $\Xi^{(r)}$ on $V_\tau$.

It is clear that we also may view $(\Lambda, \zeta) \in u(n) \times u(n)$ and that any element in the latter is determined uniquely by such a pair.

We have already described the lowest level $r = 1$ in Proposition 4.7. From the list, it is clear, in our new terminology, that the following first order $\mathfrak{t}^\mathbb{C}$-types are missing (assume for simplicity that $n > 1$):

\[ r = 1: \]
\[ V_{((i,1,0,\ldots),(1,0,\ldots),-i-2)} \text{ is missing from } M_{((i,0,\ldots),0,-i-1)}, \text{ and} \]
\[ V_{((1,0,\ldots)(i,1,0,\ldots),-i-2)} \text{ is missing from } M_{(0,(i,0,\ldots),-i-1))}. \]

The following definition extends terminology from $r = 1$:

Definition 4.21. If a highest weight module $\tilde{M}(V_{(\Lambda,\zeta)})$ appears in the decomposition of some $\mathcal{F}_{2nr}$ we denote it by $\hat{M}(V_{(\Lambda,\zeta)})$.

Already, from Lemma 4.9 and Proposition 4.10, we have:

Lemma 4.22. Suppose $r < n$. Then $\mathcal{F}_{2nr}$ contains all modules
\[ \hat{M}(V_{(a_1,\ldots,a_r,0,\ldots),0,-a_1-r}) \text{ and } \hat{M}(V_{0,(b_1,\ldots,b_r,0,\ldots),-b_1-r}) \text{.} \ (4.95) \]
The \( \mathfrak{e}^C \)-type \( V_{(a_1,\ldots,a_r,1,\ldots),(1,0,\ldots),-a_1-1-r} \) is missing from the first mentioned module, and the \( \mathfrak{e}^C \)-type \( V_{(1,0,\ldots),(b_1,\ldots,b_r,0,\ldots),-1-b_1-r} \) is missing from the other.

(The last part also follows directly from (4.94).

Remark 4.23. Of course, if a \( \mathfrak{e}^C \)-type is missing, many more \( \mathfrak{e}^C \)-types are also missing. The stated ones are in an obvious sense the smallest amongst the missing. They become highest weight spaces in generalized Verma modules in which all the \( \mathfrak{e}^C \)-types are missing from the initial module.

We will now consider a module

\[
\hat{M}(V_{((i_1,\ldots,i_x,0,\ldots),(j_1,\ldots,j_y,0,\ldots),\lambda_\beta,\zeta)})
\] (4.96)

with, by convention, \( x < n, y < n \). Preparing for cases where \( r \geq 2n \), we need to introduce two extra integers \( x \leq \bar{x} \leq n \) and \( y \leq \bar{y} \leq n \) to fully accommodate this situation. We utilize the structures defined in (4.39):

\[
\bar{x} := \max\{i = 1, \ldots, n \mid a_i \neq 0\}, \text{ and } (4.97)
\]

\[
\bar{y} := \max\{j = 1, \ldots, n \mid b_j \neq 0\}. (4.98)
\]

Theorem 4.24. If a module

\[
\hat{M}(V_{((i_1,\ldots,i_x,0,\ldots),(j_1,\ldots,j_y,0,\ldots),\lambda_\beta,\zeta)})
\] (4.99)

with \( x < n, y < n \) appears in \( \mathcal{F}_{2nr} \), then there exist integers \( a_1 \geq \cdots a_{\bar{x}} > 0 \) and integers \( b_1 \geq \cdots b_{\bar{y}} > 0 \) such that

\[
\bar{x} + \bar{y} \leq r \text{ and } \bar{x}, \bar{y} \leq n,
\] (4.100)

and such that

- If \( \bar{x} \leq n-1 \):
  \[ x = \bar{x} \text{ and } i_k = a_k, k = 1, \ldots, x. \] (4.101)

- If \( \bar{y} \leq n-1 \):
  \[ y = \bar{y} \text{ and } j_k = b_k, k = 1, \ldots, y. \] (4.102)

- If \( \bar{x} = n \):
  \[ \exists x \in \{1, \ldots, n-1\} : a_1 > \cdots > a_x > a_{x+1} = a_{x+2} = \cdots = a_n; i_1 = a_1 - a_n, \ldots, i_{n-1} = a_{n-1} - a_n. \] (4.103)

- If \( \bar{y} = n \):
  \[ \exists y \in \{1, \ldots, n-1\} : b_1 > \cdots > b_y > b_{y+1} = b_{y+2} = \cdots = b_n; j_1 = b_1 - b_n, \ldots, j_{n-1} = b_{n-1} - b_n. \] (4.104)

In all cases:

\[
\lambda_\beta = -a_1 - b_1 - r \text{ and } \zeta = a_1 + \cdots + a_{\bar{x}} - b_1 - \cdots - b_{\bar{y}}. \] (4.105)

Observe that \(-a_1 - b_1 - r = -i_1 - j_1 - r - (a_1 - a_n) - (b_1 - b_n) \leq -i_1 - j_1 - r.\n
The representations \( \hat{M}(V_{((i_1,\ldots,i_x,0,\ldots),(j_1,\ldots,j_y,0,\ldots),\lambda_\beta,\zeta)}) \) are irreducible and unitarizable.

All modules satisfying these constraints are obtained. (The multiplicities are determined later in Theorem 4.39).

If \( \bar{x} = n \) or \( \bar{y} = n \) we have that

\[
\hat{M}(V_{((i_1,\ldots,i_x,0,\ldots),(j_1,\ldots,j_y,0,\ldots),\lambda_\beta)}) = M(V_{((i_1,\ldots,i_x,0,\ldots),(j_1,\ldots,j_y,0,\ldots),\lambda_\beta)}) \] (4.106)
and no $\mathfrak{t}^C$-types are missing.

Suppose from here on that $\bar{x} < n$ and $\bar{y} < n$. Then $\bar{x} = x$ and $\bar{y} = y$ and $x + y \leq r$. If $x + y = r$ the first order $\mathfrak{t}^C$-type $((i_1, \ldots, i_x, 1, 0, \ldots), (j_1, \ldots, j_y, 1, 0, \ldots), -i_1 - j_1 - x - y)$ is missing.\footnote{If $x = n - 1$ or $y = n - 1$ this is then not of the form we usually insist on. We refrain from changing it since it is utterly clear how to do it.}

In this case,

$$
\hat{M}(V((i_1, \ldots, i_x, 0, \ldots), (j_1, \ldots, j_y, 0, \ldots), -i_1 - j_1 - x - y)) = \frac{M(V((i_1, \ldots, i_x, 0, \ldots), (j_1, \ldots, j_y, 0, \ldots), -i_1 - j_1 - x - y))}{M(V((i_1, \ldots, i_x, 1, 0, \ldots), (j_1, \ldots, j_y, 1, 0, \ldots), -i_1 - j_1 - x - y))}.
$$

More generally, define $r_0$ by $x + y = r_0 \leq r$. Assume for clarity that $x \geq y$; the case $y > x$ follows analogously.

In this case, the representation

$$
\hat{M}(V((i_1, \ldots, i_x, 0, \ldots), (j_1, \ldots, j_y, 0, \ldots), -r_0 - i_1 - j_1 - i) , i = 0, 1, \ldots, n - x - 1
$$

is missing the $(i + 1)$th order $\mathfrak{t}^C$-type

$$
V((i_1, \ldots, i_x, 1, \ldots, 1, 0, \ldots, 0), (j_1, \ldots, j_y, 1, \ldots, 1, 0, \ldots, 0), -r_0 - i - i_1 - j_1).
$$

In this case,

$$
\hat{M}(V((i_1, \ldots, i_x, 0, \ldots), (j_1, \ldots, j_y, 0, \ldots), -i_1 - j_1 - x - y)) = \frac{M(V((i_1, \ldots, i_x, 0, \ldots), (j_1, \ldots, j_y, 0, \ldots), -i_1 - j_1 - r_0 - i))}{M(V((i_1, \ldots, i_x, 1, 0, \ldots, 0), (j_1, \ldots, j_y, 1, 0, \ldots, 0), -r_0 - i - i_1 - j_1)).}
$$

The representations

$$
M(V((i_1, \ldots, i_x, 0, \ldots), (j_1, \ldots, j_y, 0, \ldots), \lambda_{\beta})), \lambda_{\beta} < -n - y + 1 - i_1 - j_1
$$

are not missing any $\mathfrak{t}^C$-types.

Proof:

First assume that $r < n$.

The $Gl(n, \mathbb{C})_L^X$ representations come from the space of polynomials in the variables $A_1^j, i = 1, \ldots, n; j = 1, \cdots, r$. We here take tensor products of $U(n)$ representations corresponding to the various columns $j = 1, \ldots, r$;

$$
V((a_1, 0, \ldots, 0) \otimes V((a_2, 0, \ldots, 0) \otimes \cdots \otimes V((a_r, 0, \ldots, 0).
$$

Any such tensor product is a sub-representation of the tensor product of $a = a_1 + a_2 + \cdots a_r$ copies of the defining representation. The latter may be represented by any $A_1^j, j = 1, \cdots, r$, or a Young diagram with just one box. Any irreducible summand of \((4.112)\) is then represented by a Young diagram with $a$ boxes. Suppose an irreducible summand has highest weight $(i_1, \cdots, i_x, 0, \cdots)$. Then, evidently, $x \leq r$, and its highest weight vector is of the form $(A_1^1(1))^{a_1} \cdots (A_1^r(1))^{a_r} \cdot p$, where $p$ contains no elements of the form $(A_1^i(i))$ and where, obviously, $\alpha_1 + \cdots + \alpha_r = i_1$.
conclusion. A similar statement can be made for the \( \text{Gl}(n, \mathbb{C})^Y_L \) representation, whose highest weight vector is a sum of terms of the form \( (A_{n+1}^\dagger(1))^{\beta_1} \cdots (A_{n+1}^\dagger(r))^{\beta_r} \cdot \hat{p} \), where \( \hat{p} \) contains no elements of the form \( (A_{n+1}^\dagger(i)) \), and where \( \beta_1 + \cdots + \beta_r = j_1 \).

The tensor product of a \( \text{Gl}(n, \mathbb{C})^X_L \) representation and a \( \text{Gl}(n, \mathbb{C})^Y_L \) representation is similarly describable and we get a module \( V_{((i_1, \ldots, i_x, 0, \ldots), (j_1, \ldots, j_y, 0, \ldots), \lambda, \zeta)} \). Let us say that the \( \text{Gl}(n, \mathbb{C})^Y_L \) representation occurs inside the tensor product of \( b = b_1 + b_2 + \cdots + b_r \) copies of the defining representation so that it is represented by a Young diagram with \( b \) boxes. We now assume that our \( \text{Gl}(n, \mathbb{C})^X_L \times \text{Gl}(n, \mathbb{C})^Y_L \) module belongs to a top pluri-harmonic vector \( v_{(\Lambda, \zeta)} \). From the above, it follows that \( H^{(r)}_\beta \cdot v_{2nr} = (−i_1 − j_1 − r)p \cdot v_{2nr} \), and \( \zeta = i_1 + \cdots + i_x − j_1 − \cdots − j_y \). Here, \( i_1 + \cdots + i_x = a, j_1 + \cdots + j_y = b, i_1 = \alpha_1 + \cdots + \alpha_r \) and \( j_1 = \beta_1 + \cdots + \beta_r \), where \( (A_{n+1}^\dagger(1))^{\alpha_1} \cdots (A_{n+1}^\dagger(r))^{\alpha_r} \) is the total contribution of \( A_{n+1}^\dagger(k) \)'s to the highest weight vector.

Since the representation defined by \( v_{(\Lambda, \zeta)} \) is unitarity, we have that \(-i_1 − j_1 − r ≤ \lambda_{\text{crit}} \). From (4.94) we then get

\[
- i_1 − j_1 − r \leq - i_1 − j_1 − x − y, \text{ hence } \quad x + y \leq r. \tag{4.113}
\]

Also, by the assumptions on \( p \),

\[
\lambda_\beta = −i_1 − j_1 − r \text{ and } \zeta = i_1 + \cdots + i_x − j_1 − \cdots − j_y. \tag{4.115}
\]

If \( r \geq n \), using an idea from (26), we choose \( N > r \) and embed \( su(n, n) \hookrightarrow su(N, N) \) as the top left corner. If \( p \cdot v_{2nr} \) is a highest weight vector for \( su(n, n) \), where \( p \) is a polynomial in the variables \( A_i^\dagger(j), i = 1, \ldots, n \) and \( j = 1, \ldots, r \), then \( p \cdot v_{2nr} \) is a highest weight vector for any \( su(N, N) \) with \( N > n \) which follows by looking at the form of the elements \( E_\beta, E_\mu, \) and \( E_\nu \) in Definition 3.19.

Using the proof of the case \( r < n \) we get a representation of \( U(N) \times u(N) \)

\[
V_{((a_1, \ldots, a_x, 0, \ldots), (b_1, \ldots, b_y, 0, \ldots), \lambda_\beta, \zeta)}, \tag{4.116}
\]

where \( x + y ≤ N \), but where also, by construction, we have \( \tilde{x}, \tilde{y} ≤ n \). Similarly we have

\[
\lambda_\beta = −a_1 − b_1 − r \text{ and } \zeta = a_1 + \cdots + a_x − b_1 − \cdots − b_y. \tag{4.117}
\]

If \( \tilde{x} = n \) or \( \tilde{y} = n \), or both, there remains the task of bringing the representation in (4.116) into a form as in (4.99), and this is straightforward.

Irreducibility of the modules \( \hat{M} \) comes from Proposition 4.20.

That the representations all occur follows by explicitly exhibiting highest weight vectors. See Corollary 4.31 later.

Let us now examine if there are missing \( t^\mathbb{C} \)-types in the cases where either \( \tilde{x} = n \), \( \tilde{y} = n \), or both. The strategy is similar, so we only do \( \tilde{x} = n, \tilde{y} < n \). Then \( r ≥ n + y \).
Missing $\mathfrak{g}^\mathbb{C}$-types would easily lead to a homomorphism between generalized Verma modules

$$M(V_{\Lambda_2}) \to M(V_{\Lambda}).$$

(4.118)

Now we recall the famous BGG Theorem; see ([2], [3]), and also ([18, Proposition 3.6]).

**Proposition 4.25** (BGG). If there is a homomorphism $M(V_{\Lambda_1}) \to M(V_{\Lambda})$ then the following condition (A) is satisfied:

(A) There exists a sequence of positive non-compact roots $\gamma_1, \cdots, \gamma_s$ such that

$$\Lambda_1 + \rho = \sigma_{\gamma_s} \circ \cdots \circ \sigma_{\gamma_1}(\Lambda + \rho)$$

(4.119)

and such that ($\sigma_{\gamma_0} = I_d$) $\sigma_{\gamma_i} \circ \cdots \circ \sigma_{\gamma_1}(\Lambda + \rho) - \sigma_{\gamma_{i-1}} \circ \cdots \circ \sigma_{\gamma_1}(\Lambda + \rho) = -n_i \gamma_i$

with $n_i \in \mathbb{N}$ for $i = 1, \ldots, s$.

In particular, $\Lambda_1 = \Lambda - n_1 \gamma_1 - \cdots - n_s \gamma_s$. Furthermore, since inner products between positive non-compact roots are positive, $(\Lambda + \rho)(H_{\gamma_i}) > 0$ for all $i = 1, \ldots, s$.

Consider now a positive non-compact root $\gamma_I = \beta + \mu_1 + \cdots + \mu_{a_i - 1} + \nu_1 + \cdots + \nu_{b_i - 1}$ and assume it is the first in a sequence as in condition (A) above. We get from the last condition in the above proposition;

$$i_1 - i_{a_i} + j_1 - j_{b_i} + (a_i - 1) + (b_i - 1) + \lambda + 1 = n_1 \in \mathbb{N}.$$ 

(4.120)

Since $\lambda = -i_1 - j_1 - r - c$ for some $c \in \mathbb{N}$ and since $r \geq n + y$, this leads to

$$a_i + b_i = n_i + i_a + j_{b_i} + 1 + c + r \geq n_i + 1 + c + n + y.$$ 

(4.121)

Furthermore, $a_i + b_i \leq n + b_i$, and hence

$$\forall i : b_i \geq 3 + y.$$ 

(4.122)

But then $\Lambda_1(H_{\nu_{y+1}} + \cdots + H_{\nu_{y-1}}) < 0$ contradicting that $\Lambda_1$ is a highest weight for a finite dimensional representation. Hence there can be no missing $\mathfrak{g}^\mathbb{C}$-types in this domain.

Let us finally return to the case $\tilde{x} = x, \tilde{y} = y$. Of course, when $x + y = r$ (then $\lambda = \lambda_{crit}$), a first order polynomial is missing.

It follows that this $\mathfrak{g}^\mathbb{C}$ type is in the radical of the Hermitian form. Now we invoke the results from ([6], [8]), or ([20]) that give that this radical is a generalized Verma module.

Finally observe that

$$\hat{M}(V_{((i_1, \ldots, i_x, 0, \ldots), (j_1, \ldots, j_y, 0, \ldots), -r_0 - i_1 - j_1 - i)} \subset$$

$$\hat{M}(V_{((i_1, \ldots, i_x, 0, \ldots), (j_1, \ldots, j_y, 0, \ldots), -r_0 - i_1 - j_1)} \otimes \hat{M}(V_{0, 0, -i}) i = 1, \ldots, n - x - 1.$$ 

(4.124)

Since $\hat{M}(V_{0, 0, -i})$ is missing all $(i + 1) \times (i + 1)$ minors, the claim follows easily along the same line as for the case $x + y = r$.

This completes the proof of Theorem 4.24.

**Corollary 4.26**. The representations with missing $\mathfrak{g}^\mathbb{C}$-types in Theorem 4.24 are exactly those that, via duality, define covariant differential operators whose null spaces carry unitary representations.
Definition 4.27. If \( \hat{M}(V_{(i_1, \ldots, i_x, 0, \ldots), (j_1, \ldots, j_y, 0, \ldots)}; \lambda, \zeta) \) as above appears in \( F_{2nr} \), in the same notation as above, we associate a highest weight representation of \( u(r) \) of highest weight
\[
(\Lambda, \zeta)_{u(r)} := (a_1, \ldots, a_{\tilde{x}}, 0, \ldots, 0, -b_{\tilde{y}}, \ldots, b_1).
\] (4.125)

The reason for this will become clear later. We may also refer to \( (\Lambda, \zeta)_{u(r)} \) as the irreducible representation of \( u(r) \) determined by \( (\Lambda, \zeta) \).

Recall that the \( \mathfrak{t}^\mathbb{C} \)-types always can be assumed to be of the form
\[
\Lambda = ((i_1, \ldots, i_x, 0, \ldots), (j_1, \ldots, j_y, 0, \ldots), \lambda_\beta, \zeta) \text{ with } x, y < n. \tag{4.126}
\]

As an aside, notice that this convention is different from that of \([26]\).

4.7. Generalized Verma modules and tensor products thereof. To deal with the question of multiplicities, we first go through some general theory. To begin we return to the general set-up as in Subsection 4.5.

Let \( \{W_\alpha\}_{\alpha \in A} \) and \( \{Z_\alpha\}_{\alpha \in A} \) be bases of \( \mathfrak{p}^- \) and \( \mathfrak{p}^+ \), respectively, and assume that \( \forall \alpha : Z_\alpha = -\omega(W_\alpha) \). In our later application, \( \mathfrak{p}^\pm \) are representable by the space of \( n \times n \) complex matrices.

The following method was discovered by S. Martens \([32]\). It was further developed, independently, of Jakobsen–Vergne. Here we go one step further and describe the dual version:

We assume given two highest weight modules \( \hat{M}(V_{\tau_1}), \hat{M}(V_{\tau_2}) \) that are top quotients in their corresponding generalized Verma Modules. We wish to decompose \( \hat{M}(V_{\tau_1}) \otimes \hat{M}(V_{\tau_2}) \).

As a \( \mathfrak{t}^\mathbb{C} \)-module we have a decomposition into irreducible submodules
\[
V_{\tau_1} \otimes V_{\tau_2} = \oplus_{i=1}^{2^N} V_{\tilde{\tau}_i}. \tag{4.127}
\]

Let
\[
W_\alpha^L = W_\alpha \otimes 1, \quad W_\alpha^R = 1 \otimes W_\alpha, \quad \text{and} \quad Y_\alpha = W_\alpha^L - W_\alpha^R (\alpha \in A). \tag{4.128}
\]

and, for each \( \ell \), let \( \mathcal{P}_\ell(Y, V_{\tilde{\tau}_i}) \) denote the span of all expressions
\[
Y_{\alpha_1}Y_{\alpha_2}\cdots Y_{\alpha_k}v_{\tilde{\tau}_i} \in \hat{M}(V_{\tau_1}) \otimes \hat{M}(V_{\tau_2}) \tag{4.129}
\]

with \( k \leq \ell \) and \( v_{\tilde{\tau}_i} \in V_{\tilde{\tau}_i} \).

It is clear that they transform under \( \mathfrak{t}^\mathbb{C} \) according to a sub-representation of \( V_{\tilde{\tau}_1} \otimes V_{\tilde{\tau}_2} \otimes \mathcal{U}(\mathfrak{p}^-) \). As we shall see, it may happen that this, due to cancellations, is a proper sub-representation.

One has a filtration of \( \mathfrak{t}^\mathbb{C} \) modules
\[
\emptyset \subseteq \mathcal{P}_0(Y, V_{\tilde{\tau}_i}) \subseteq \mathcal{P}_1(Y, V_{\tilde{\tau}_i}) \subseteq \cdots \subseteq \mathcal{P}_\ell(Y, V_{\tilde{\tau}_i}) \subseteq \cdots.
\]

It is straightforward to see that the elements \( X_\alpha = (Z_\alpha \otimes 1 + 1 \otimes Z_\alpha) \) have the following property:
\[
\forall j, \forall \alpha \in A; X_\alpha : \mathcal{P}_{\ell}(Y, V_{\tilde{\tau}_i}) \to \mathcal{P}_{\ell-1}(Y, V_{\tilde{\tau}_i}). \tag{4.130}
\]
This easily has the following consequence:

**Proposition 4.28.** For each ℓ, τ_i, let R_ℓ(Ṽ_τ_i) denote the U module obtained by letting elements u ∈ U act through the co-product Δ(u) on P_ℓ(Y, Ṽ_τ_i) from the left. Then we have a U filtration of \( \tilde{M}(V_{τ_1}) \otimes \tilde{M}(V_{τ_2}) \):

\[
\emptyset \subseteq R_0(V_{τ_1}) \subseteq R_1(V_{τ_1}) \subseteq \cdots \subseteq R_ℓ(V_{τ_1}) \subseteq \cdots \subseteq \tilde{M}(V_{τ_1}) \otimes \tilde{M}(V_{τ_2}).
\]

(4.131)

The quotient modules \( R_{\ell+1}(V_{τ_1})/R_\ell(V_{τ_1}) \) are finite sums of top quotients \( \tilde{M}(V_ξ) \) where

\[ ξ \text{ occurs in } V_{τ_1} \otimes V_{τ_2} \otimes (p^-)^{≤_\ell+1}. \]

(4.132)

Here \( p^- \) is spanned by the elements \( Y_α \) (4.128). However, we may also choose elements from just \( p^-_L \) or from \( p^-_R \), the spaces generated by the elements \( W_α^L \) and \( W_α^R \), respectively.

The last statement in the proposition is true since we are working modulo expressions generated by the elements \( W_α^L + W_α^R \), so \( Y_α \) is equivalent to the left or right expressions.

It is clear that

\[ R_0(V_{τ_1}) = \tilde{M}(V_{τ_1}) \]

(4.133)

for some top quotient \( \tilde{M}(V_{τ_1}) \).

Analogous statements hold at the higher levels except that there is a major new feature which can be seen already at degree 1: Each of the modules \( R_1(V_{τ_1}) \) is sum of modules of the form \( \tilde{M}(V_{τ_{i,1}}) \) where \( V_{τ_{i,1}} \) occurs in \( V_{τ_i} \otimes p^- \), but it may happen, as we shall see below, that there may be an irreducible summand \( V_{τ_{i,1}} \) from the latter for which no top quotient \( \tilde{M}(V_{τ_{i,1}}) \) occurs in the decomposition of \( R_1(V_{τ_i})/R_0(V_{τ_i}) \). In this case we say that the highest weight module of highest weight \( Λ_{τ_i} \) is missing from \( \tilde{M}(V_{τ_1}) \otimes \tilde{M}(V_{τ_2}) \). A related problem which we shall only partially discuss is that of determining which U(\( \mathfrak{t}^C \)) representations that actually do occur in the tensor product.

**Definition 4.29.** A \( \mathfrak{t}^C \)-type \( V_ξ \) appears at level \( d \) in \( \tilde{M}(V_{τ_1}) \otimes \tilde{M}(V_{τ_2}) \) if it is a non-zero \( \mathfrak{t}^C \)-type in the quotient of \( P_d(Y) \otimes V_{τ_1} \otimes V_{τ_2} \) modulo the U-modules generated by all (non-zero) elements in all \( P_{d'}(Y) \otimes V_{τ_1} \otimes V_{τ_2} \) with \( d' < d \).

4.8. **Multiplicities.** To determine multiplicities, we now invoke the commuting algebra \( U(u(r)) \). Specifically, the action of \( u(r) \) given in (4.20). This method is inspired by (20).

The span \( TP(Λ) \) of the set of top pluri-harmonic vectors \( v_Λ \) of a given weight \( Λ \) is invariant \( U(u(r)) \), but when \( r ≥ 2n \) this space needs not be irreducible. The dimension \( \dim_{u(r)}(Λ) = \dim TP(Λ) \) gives the multiplicity of the \( su(n,n)^C \) module of highest weight \( Λ \). To handle this situation, we need to be more precise and turn to the space \( TP((Λ, ζ)) \) of top pluri-harmonic vectors \( v_{(Λ, ζ)} \) of a given weight \( (Λ, ζ) \).
This space will always define an irreducible representation \((\Lambda, \zeta)_{u(r)}\) of \(u(r)\), but, as we shall see, if \(r > n\) these representations will not exhaust \(u(r)\).

We have

\[
\mathcal{T} \mathcal{P}(\Lambda) = \bigoplus_{\zeta} \mathcal{T} \mathcal{P}((\Lambda, \zeta)) .
\] (4.134)

The sum over \(\zeta\) above is finite. \(\zeta\) is essentially determined as in (4.49). See also (4.136) and further below.

We now embark on the details of this:

**Proposition 4.30.** Let \(p\) be top pluri-harmonic polynomial of weight \((\Lambda, \zeta)\) and let \(\tilde{x}, \tilde{y}\) be as in Theorem 4.24. Then \(\tilde{x} + \tilde{y} \leq r\). Set

\[
\mathbf{n} = (n_1, \ldots, n_{\tilde{x}}, 0, \ldots, 0) \quad \text{and} \quad \mathbf{m} = (m_1, \ldots, m_{\tilde{y}}, 0, \ldots, 0). \quad (4.135)
\]

In the cyclic \(GL^D_R(r, \mathbb{C})\) module generated by \(p\) there is a polynomial \(p^T = \Delta^a(x) \tilde{\Delta}(y)^m\) such that \(p^T \cdot v_{2nr}\) is a highest weight vector of the same weight \((\Lambda, \zeta)\) as \(p\). The \(gl^D_R(r, \mathbb{C})\) module of top pluri-harmonic vectors of weight \((\Lambda, \zeta)\) is irreducible of highest weight

\[
(\Lambda, \zeta)_{u(r)} = (n_1, \ldots, n_{\tilde{x}}, 0, \ldots, 0, -m_{\tilde{y}}, \ldots, -m_1). \quad (4.136)
\]

**Proof.** We prove this by induction. The case \(r = 1\) is clear. Consider then an irreducible representation \(\tilde{M}(V_{(\Lambda_{r+1}, \zeta_{r+1})})\) in \(\mathcal{F}_{2n(r+1)}\) with highest weight vector \(p_{(\Lambda_{r+1}, \zeta_{r+1})}\).

We know that \(\tilde{M}(V_{(\Lambda_{r+1}, \zeta_{r+1})}) \subseteq \tilde{M}(V_{(\Lambda_r, \zeta_r)}) \otimes \tilde{M}(V_{(\Lambda_1, \zeta_1)})\) (by unitarity it is a summand) where \(\tilde{M}(V_{(\Lambda_r, \zeta_r)})\) comes from \(\mathcal{F}_{2nr}\) and \(\tilde{M}(V_{(\Lambda_1, \zeta_1)})\) comes from \(\mathcal{F}_{2n}\). Without loss of generality we may assume that \(V_{(\Lambda_1, \zeta_1)} = V_{(a, 0, \ldots, 0, \lambda = -a - 1, \zeta = a)}\) for some integer \(a \geq 0\).

We view \(GL^D_R(r, \mathbb{C})\) embedded in \(GL^D_R(r + 1, \mathbb{C})\) in the top left \(r \times r\) positions with the auxiliary entries set equal to 0 except the \((r + 1), (r + 1)\) entry which is set to 1.

We may assume, by the induction assumption, that \(\tilde{M}(V_{(\Lambda_r, \zeta_r)})\) is represented by a highest weight vector

\[
p_{(\Lambda_r, \zeta_r)} \cdot v_{2nr} = u \cdot p^T_{(\Lambda_r, \zeta_r)} \cdot v_{(\Lambda_r, \zeta_r)} \quad (4.137)
\]

for some \(u \in \mathcal{U}(gl^D_R(r, \mathbb{C}))\). Using Proposition 4.28 we know that it suffices, for \(p_{(\Lambda_{r+1}, \zeta_{r+1})} \cdot v_{2n(r+1)}\), to look at the tensor products of vectors from the \(\mathfrak{e}^C = \mathcal{U}(u(n)^C) \times \mathcal{U}(u(n)^C)\) type corresponding to \(p_{(\Lambda_r, \zeta_r)}\) with vectors coming from \(\tilde{M}(V_{(\Lambda_1, \zeta_1)})\).

The element \(u\) in (4.137) only depends on the variables in the aforementioned upper left \(r \times r\) corner (when identifying \(gl^D_R(r + 1, \mathbb{C})\) with \(gl^D(r + 1, \mathbb{C})\)). By assumption we see that we may write

\[
p_{(\Lambda_{r+1}, \zeta_{r+1})} = u \cdot \tilde{p}_{r, i, x}(x_{11}, \ldots, x_{n \tilde{x}}) \tilde{p}_{r, i, y}(y_{1, r-\tilde{y}+1}, \ldots, y_{n, r}) \tilde{p}_{r+1, i}(x_{1, r+1}, \ldots, x_{n, r+1}, y_{1, r+1}, \ldots, y_{n, r+1}) := \quad (4.138)
\]

\[
u \cdot \tilde{p}_{(\Lambda_{r+1}, \zeta_{r+1})} \quad (4.139)
\]

with \(\tilde{x} + \tilde{y} \leq r\). The \(u\) is in \(gl^D_R(r, \mathbb{C}) \subseteq gl^D_R(r + 1, \mathbb{C})\).
We analyze the expression \( \tilde{p}(\Lambda_{r+1}, \zeta_{r+1}) \) in the bracket in the above equation.

We do induction in the \( y \) degrees of the second term. The degree 0 is clear by the Littlewood-Richardson Rule (4.12). \( \tilde{p}(\Lambda_{r+1}, \zeta_{r+1}) \) now is pluri-harmonic modulo the (repeated) action of expressions \( W^L_\alpha + W^R_\alpha \) on lower order degrees \( p_{\text{lower}} \). By induction, \( p_{\text{lower}} \) can be brought to the desired form \( \Delta^{\tilde{n}}(x) \Delta(y)^m \) for some \( \tilde{n}, \tilde{m} \) by \( GL^D_R(r+1, \mathbb{C}) \). Moreover, \( GL^D_R(r+1, \mathbb{C}) \) commutes with the elements \( W^L_\alpha + W^R_\alpha \).

We now show that \( \tilde{p}(\Lambda_{r+1}, \zeta_{r+1}) \) can be brought into a similar form \( \Delta^{\tilde{n}}(x) \Delta(y)^m \) by the action of \( GL^D_R(r+1, \mathbb{C}) \). Suppose first that \( \tilde{x} + \tilde{y} = r \). Also assume \( \tilde{x} \neq 0 \). Use first the permutation \( \sigma_{\tilde{x}+1,r+1} \) of columns \( \tilde{x} + 1 \) and \( r + 1 \). Clearly, \( \sigma_{\tilde{x}+1,r+1} \in GL^D_R(r+1) \). If \( \tilde{x} = 0 \), this step is not needed. After that we have polynomials in \( X \) which depend on the first \( x + 1 \) columns multiplied with polynomials in \( Y \) which depend on the columns \( x + 1, \ldots, r + 1 \). Observe that the operators \( E_\mu \) and \( O_{ij} \) (of (4.20)), \( j > i \) “pushes” towards \((A_1(1))^\dagger \) while the operators \( E_\nu \) and \( O_{ij}, j > i \) “pushes” towards \((A_{n+1}(r))^\dagger \).

Indeed, the elements in \( GL^D_R(r+1, \mathbb{C}) \) we utilize in bringing the polynomials in \( X \) to the desired corner position (using Corollary 4.4), are of the form

\[
\sum_{a=1}^n \left( x_{a,i} \frac{\partial}{\partial x_{a,j}} - y_{a,j} \frac{\partial}{\partial y_{a,i}} \right) \quad \text{with} \quad x + 1 \geq j > i \geq 1,
\]

hence they will give zero when applied to polynomials in \( Y \) which are zero in the first \( x \) columns. This means that we can bring these polynomials into the corner position in the \( X \) variables without affecting the \( Y \) variables and vice versa. So, we can bring the \( X \) variables into corner form covering the first \( x + 1 \) columns and the \( y \) variables into corner form covering the last \( y + 1 \) columns. We then arrive at a vector 

\[
\Delta^{\tilde{n}}(x) \Delta(y)^m \cdot v_{2nr}
\]

which is a highest weight vector for \( \mathfrak{t}^C \) as well as \( GL^D_R(r+1, \mathbb{C}) \). The assumption is that, additionally, this is top pluri-harmonic modulo lower orders. Especially, the data \( \tilde{n}, \tilde{m} \) corresponds to \( (\Lambda_{r+1}, \zeta_{r+1}) \), and falls under Theorem 4.24 to allow us to conclude that either the \( X \) variables actually are bound only to the \( x \) first columns (then the \( Y \) variables will be supported on the last \( y + 1 \) columns) or the \( Y \) variables are tied only to the last \( y \) columns (with the \( X \) variables supported on the first \( x + 1 \) columns).

The case where \( \tilde{x} + \tilde{y} < r \) is clear since then there is a position \( \ell \) with \( \tilde{x} < \ell < r + 1 - \tilde{y} \) and we can use a permutation from \( GL^D_R(r+1, \mathbb{C}) \) that interchanges \( \ell \) and \( r + 1 \). After that, follow the same proof.

It follows easily that also \( p(\Lambda_{r+1}, \zeta_{r+1}) \) can be brought into the form \( \Delta^{\tilde{n}}(x) \Delta(y)^m \).

Finally, by easy inspection, the top term \( \Delta^{\tilde{n}}(x) \Delta(y)^m \) is pluri-harmonic. Hence the lower order terms are actually 0.

We finally need to address the irreducibility of the representation of \( GL^D_R(r+1, \mathbb{C}) \): The element \( \Delta^{\tilde{n}}(x) \Delta(y)^m \cdot v_{2nr} \) in Proposition 4.30 is evidently a highest weight vector for \( gL^D_R(r+1, \mathbb{C}) \) of weight \( (n_1, \ldots, n_{\tilde{x}}, 0, \ldots, 0, -m_{\tilde{y}}, \ldots, -m_1) \), hence defines an irreducible finite-dimensional representation of \( gL^D_R(r+1, \mathbb{C}) \). Notice that \( \Delta^{\tilde{n}}(x) \cdot v_{2nr} \) is a highest weight vector for \( GL(n, \mathbb{C})_L^X \times GL(r, \mathbb{C})_R^X \) and \( \Delta(y)^m \cdot v_{2n(r+1)} \)
is a highest weight vector for $GL(n, \mathbb{C})^Y_L \times GL(r, \mathbb{C})^Y_R$ (The latter acting by $(u^T)^{-1}$, c.f. [4.17]). The representation of $gl^D_R(r + 1, \mathbb{C})$ thus has a highest weight vector, and this is uniquely, and explicitly, determined by the $\mathfrak{gl}$ type involved, i.e. by the highest weight $(\Lambda, \zeta)$. It follows that the representation of $GL^D_R(r + 1, \mathbb{C})$ in the space of top pluri-harmonics of type $(\Lambda, \zeta)$ is irreducible. \hfill $\Box$

Quite generally, any element $\Delta^n(x) \Delta(y)^m \cdot v_{2nr}$ in $F_{2nr}$ defines an irreducible $GL^D_R(r, \mathbb{C})$ module and, if the variables $x, y$ do not overlap, it is also a top pluri-harmonic vector of a weight $(\Lambda, \zeta)$ directly given $(n_1, \cdots, n_{\tilde{x}}, 0, \cdots, 0, -m_{\tilde{y}}, \ldots, -m_1)$.

**Corollary 4.31.** All the representations of Theorem 4.24 appear in the decomposition.

*Proof:* This follows from Lemma 4.22 by forming tensor products between representations in which $x = 0$ with representations in which $y = 0$. \hfill $\Box$

To finally settle the question of multiplicities we need one more step in our analysis: This is because of the appearance of $\zeta$.

From now on, we identify $gl^D_R(r, \mathbb{C})$ with $gl(\mathbb{C})$. Observe that any highest weight $\xi_{gl(\mathbb{C})}$ of $gl(r, \mathbb{C})$ can be written uniquely as

$$\xi_{gl(r, \mathbb{C})} = (a_1, n_2, \cdots, a_{\tilde{x}}, 0, \cdots, 0, -b_{\tilde{y}}, -b_{\tilde{y}-1}, \cdots, -b_1)$$

(4.141)

with $a_1 \geq a_2 \geq \cdots \geq a_{\tilde{x}} > 0$ and $b_1 \geq b_2 \geq \cdots \geq b_{\tilde{y}} > 0$. The cases $\tilde{x} = 0$ or $\tilde{y} = 0$ are allowed and mean that the string $a_1, \cdots, b_1, \cdots$, is not present.

We must then demand $\tilde{x} \leq n$ and $\tilde{y} \leq n$ for $\Lambda_{gl(r, \mathbb{C})}$ to correspond to a top pluri-harmonic representation. This is necessary when $r > n$. We set $\mathbf{a} = (a_1, \cdots, a_n)$ where, if $\tilde{x} < n$, we set $a_k = 0$ for $\tilde{x} < k \leq n$. The symbol $\mathbf{b} = (b_1, \cdots, b_n)$ is defined analogously. Further, we set $|\mathbf{a}| = a_1 + \cdots + a_n$, and $|\mathbf{b}| = b_1 + \cdots + b_n$.

**Definition 4.32.** $\Sigma_n^{(r)}$ denotes those irreducible representations of $gl(r, \mathbb{C})$ for which, in (4.141), $\tilde{x}, \tilde{y} \leq n$.

*Given* $\xi = \xi_{u(r)} \in \Sigma_n^{(r)}$, *written as in (4.141)*, *we set*

$$(\Lambda, \zeta)^\xi = (i_1, \cdots, i_{\tilde{x}}, 0, \cdots, (j_1, \cdots, j_{\tilde{y}}, 0, \cdots), \lambda_\beta, \zeta)$$

where $$(i_1, \cdots, i_{\tilde{x}}, 0, \cdots) = (a_1 - a_n, \cdots, a_{n-1} - a_n, 0),$$

$$(j_1, \cdots, j_{\tilde{y}}, 0, \cdots) = (b_1 - b_n, \cdots, b_{n-1} - b_n, 0)$$

and

$$\lambda_\beta = (-a_1 - b_1 - r, |\mathbf{a}| - |\mathbf{b}|).$$

(4.142) (4.143) (4.144) (4.145)

**Remark 4.33.** $\Sigma_n^{(r)}$ is the set $\Sigma$ of ([26]).

Notice that $-a_1 - b_1 - r = -(a_1 - a_n) - (b_1 - b_n) - r - (a_n + b_n)$. If $(a_n + b_n) > 0$, this parameter is less than the critical value.

We can reformulate Corollary 4.31.

**Corollary 4.34.** All such modules $M(V_{(\Lambda, \zeta)^\xi})$ appear in the decomposition.
For $\xi \in \Sigma^{(r)}_n$, let $\dim(\xi)$ denote the dimension. We can then state:

**Theorem 4.35** ([26]).

$$\mathcal{F}_{2nr} = \oplus_{\xi \in \Sigma^{(r)}_n} \dim(\xi) \tilde{M}(V(\Lambda, \zeta)^\xi).$$

(4.146)

This is a decomposition into irreducible unitary highest weight representations of $u(n,n)^C$. In case $r < 2n$, if $(\Lambda, \zeta)^\xi$ appears, the $\zeta$ is unique, so the formula in Theorem 4.35 also gives a decomposition into irreducible unitary highest weight representations of $su(n,n)^C$. In case $r \geq 2n$ assume that $\Phi := -\lambda - i_1 - j_1 - r \geq 0$. Furthermore, set $|i| = i_1 + \cdots + i_x$ and $|j| = j_1 + \cdots + j_y$, and let $\zeta_i = |i| - |j| + ni$. Then $(\Lambda, \zeta_i)^\xi$ appears precisely for $i = -\Phi + 2, \ldots, \Phi$.

**Proof:** This was already established in Theorem 4.24 with only the case $r \geq 2n$ missing explicitly. However, this case follows as in (4.49).

**Proposition 4.36.** The highest weight vectors are given by

$$\triangle(x)^a \tilde{\triangle}(y)^b v_{2nr}.$$ (4.147)

If $a_n \cdot b_n > 0$, the highest weight vector

$$\triangle(x)^{a-e_n} \tilde{\triangle}(y)^{b-e_n} v_{2nr}$$ (4.148)

defines an equivalent $su(n,n)$ module.

In terms of the creation operators we have

$$\forall k : \triangle_k(x) = \sum_{\sigma \in S_k} (-1)^{sgn(\sigma)} \prod_{i=1}^{k} A^\dagger_i(\sigma(i)),$$ (4.149)

and

$$\forall \ell : \tilde{\triangle}_\ell(y) = \sum_{\sigma \in S_\ell} (-1)^{sgn(\sigma)} \prod_{i=1}^{\ell} A^\dagger_{n+i}(r - \ell + (\sigma(i))).$$ (4.150)

5. The $q$-harmonic representation

We introduce the quantized version of the Weyl algebra. As in [25], we call this the Hayashi-Weyl Algebra since it was studied by Hayashi in [16]. We stress, though, that the algebra presented here is a modified, simpler version. Notably, our $q$ is the $q^2$ of [16].

**Definition 5.1** (The Hayashi-Weyl Algebra). Let $q$ be a non-zero complex number such that $q^2 \neq 1$. The algebra $HW_q$ is defined as an associative unital algebra with
generators $B_i, B_i^\dagger, L_i^{\pm 1}, i = 1, 2, \cdots, s$ and relations
\[
\begin{align*}
L_iL_j &= L_jL_i, & L_iL_i^{-1} &= L_i^{-1}L_i = 1, & (5.1) \\
B_iB_j &= B_jB_i, & B_i^\dagger B_j^\dagger &= B_j^\dagger B_i^\dagger, & (5.2) \\
B_iB_j &= B_jB_i & i \neq j, & (5.3) \\
L_iB_jL_i^{-1} &= q^{-\delta_{ij}}B_j, & L_iB_jL_i^{-1} &= q^{\delta_{ij}}B_j^\dagger, & (5.4) \\
B_iB_i^\dagger - qB_i^\dagger B_i &= L_i^{-1}, & B_iB_i^\dagger - q^{-1}B_i^\dagger B_i &= L_i. & (5.5)
\end{align*}
\]

The last pair of relations are equivalent to the following:
\[
B_iB_i^\dagger = \frac{qL_i - q^{-1}L_i^{-1}}{q - q^{-1}}, \quad B_i^\dagger B_i = \frac{L_i - L_i^{-1}}{q - q^{-1}}.
\] (5.6)

We denote by $\mathcal{HW}_s^+$ and $\mathcal{HW}_s^-$ the subalgebras generated by the elements $B_i, i = 1, \ldots, s$ and the elements $B_i^\dagger, i = 1, \ldots, s$, respectively.

When $s = 1$ we drop the subscripts.

For later reference we list the following which is easily proved by induction:

**Lemma 5.2.** For $N \in \mathbb{N}$,
\[
B(B^\dagger)^N = q^{-N}(B^\dagger)^N B + [N]_q(B^\dagger)^{N-1}L
\]
\[
= q^N(B^\dagger)^N B + [N]_q(B^\dagger)^{N-1}L^{-1}.
\] (5.7) (5.8)

**Lemma 5.3** (The $q$-Weyl-Serre Equations).
\[
(B^\dagger)^2B - (q + q^{-1})(B^\dagger BB^\dagger) + B(B^\dagger)^2 = 0,
\] (5.9)
\[
B^2B^\dagger - (q + q^{-1})(BB^\dagger B) + B^\dagger B^2 = 0.
\] (5.10)

**Remark 5.4.** More generally, any pair $(\hat{B}, \hat{B}^\dagger) = (\kappa L^a B, \tilde{\kappa}L^{-a}B^\dagger)$ satisfies the $q$-Weyl–Serre Equations, with $a \in \mathbb{Z}$ and $\kappa, \tilde{\kappa} \in \mathbb{C}^*$.

The introduced algebra has a natural - occasionally to be called defining - representation.

**Definition 5.5.** The $q$-Fock Space $\mathcal{F}_s^{(q)}$ is an infinite-dimensional space with basis \(\{e(m) \mid m \in \mathbb{N}_0^{2n}\}\) and the $q$-Stone–von Neumann representation $\pi_{s}^{qSvN}$ is a representation of $\mathcal{HW}_s$ in $\mathcal{F}_s^{(q)}$. The actions of the generators in this representation are given by
\[
L_i e(m) = q^m e(m), \quad B_i e(m) = [m]_q e(m - e_i), \quad B_i^\dagger e(m) = e(m + e_i),
\]
where $m = \{m_1, \ldots, m_s\}$ and $[m]_q = \frac{q^m - q^{-m}}{q - q^{-1}}$. Here, we set $e(m) = 0$ if $m \notin \mathbb{N}_0^{2n}$.

Notice that
\[
\pi_{s}^{qSvN} = \bigotimes_{i=1}^{s} \pi_{i}^{qSvN}.
\] (5.11)
It is obvious that the vector $v_s(q) = e(0)$ is cyclic, satisfies $L_i v_s(q) = v_s(q)$, and is annihilated by all $B_i$, $i = 1, \ldots, s$.

**Lemma 5.6.** $\pi_s^{qS_N}$ is irreducible.

**Proof.** It suffices to consider $\pi_1^{qS_N}$ for $H_N$. The operators in the representation are shift operators which, since we assume $\forall n \in \mathbb{N} : [n]_q \neq 0$, omit no positions. □

**Lemma 5.7.**

\[ \{(B^\dagger)^a L^b, B^c L^d \mid a \in \mathbb{N}_0, c \in \mathbb{N}, b, d \in \mathbb{Z}\} \quad (5.12) \]

is a basis of $H_N$.

**Proof.** Due to (5.5), it is clear that the set is spanning. Suppose that a finite linear combination

\[ p = \sum (\alpha_a (B^\dagger)^a p_a + \beta_b B^b \tilde{p}_b) = 0 \quad (5.13) \]

for some Laurent polynomials $p_a, \tilde{p}_b$. Then $\forall N \in \mathbb{N} : L^N p L^{-N} = 0$. By considering weights it follows that $\forall a : (B^\dagger)^a p_a = 0$ and $\forall b : B^b \tilde{p}_b = 0$. Suppose then that some $(B^\dagger)^a p_a = 0$. One is easily brought into a situation where

\[ X_a = (B^\dagger)^a (a_0 + a_1 L + \cdots + a_r L^r) = 0 \quad (5.14) \]

for some $r$ and some constants $a_0, \ldots, a_r$. Then $B^\dagger X_a - X_a B^\dagger = 0$ and hence

\[ (B^\dagger)^{a+1} (a_1 (1 - q) L + \cdots + a_r (1 - q^r) L^r) = 0. \quad (5.15) \]

Continuing like that, one concludes that $(B^\dagger)^R = 0$ for some $R \in \mathbb{N}$. One may then apply Lemma 5.2 to conclude that (since $q$-generic), $(B^\dagger)^{R-1} = 0$. Proceeding like that one gets the contradiction $1 = 0$. The case $B^b \tilde{p}_b = 0$ follows analogously. □

**Proposition 5.8.** $\forall s = 1, 2, \ldots, H_N$ is a simple algebra which is a domain.

**Proof.** It suffices to consider $H_N$. Suppose $p_1 \cdot p_2 = 0$ for $p_1, p_2 \in H_N$. One can easily shift this equation, if needed, to an equation $p_3 \cdot p_4 = 0$ where both elements $p_3, p_4$ are finite sums of the general form $\sum_x (B^\dagger)^x p_x$ for Laurent polynomials $p_x$. By looking at the highest powers of $B^\dagger$ one easily concludes that at least one of the factors must be 0.

Let us then consider a non-zero ideal $I$ in $H_N$, and let $p \in I$ be a non-zero element. The proof now proceeds exactly as the previous proof. The only difference is that the equations $= 0$ should be replaced by “$\in I$”. After the manipulations, one then reaches the statement $1 \in I$. This implies that $I$ is the full space. □

Equally obvious is:

**Proposition 5.9.** The following is a basis of $F_s(q)$:

\[ \{(B_1^\dagger)^{a_1} (B_2^\dagger)^{a_2} \cdots (B_s^\dagger)^{a_s} v_s(q) \mid (a_1, a_2, \ldots, a_s) \in \mathbb{N}_0^s\}. \quad (5.16) \]

**Corollary 5.10.** $\forall i : B_i^\dagger$ acts injectively on $F_s(q)$. 

37
5.1. The Hayashi-Weyl algebra and $\mathcal{U}_q(su(n,n))$. We now proceed to give an explicit homomorphism $\psi^{(1)}_q$ of $\mathcal{U}_q(su(n,n)_{\mathbb{C}})$ into $\mathcal{H}W_{2n}$. If $G_i, i = 1, \ldots, 8n - 4,$ is a set of generators of $\mathcal{U}_q(su(n,n)_{\mathbb{C}}),$ we set $\forall i : \psi^{(1)}_q(G_i) = G^{(1)}_i$ where the elements $G^{(1)}_i$ are:

**Definition 5.11.**

\[
\begin{align*}
E^{(1)}_{\beta} &= -B_1B_{n+1}, & F^{(1)}_{\beta} &= B_{1}^\dagger B_{n+1}, \\
E^{(1)}_j &= B_j^\dagger B_{j+1}, & F^{(1)}_j &= B_j^\dagger B_{j+1}, & 1 \leq j < n, \\
E^{(1)}_j &= B_j^\dagger B_{j+1}, & F^{(1)}_j &= B_jB_{j+1}, & 2n > j > n, \\
K^{(1)}_{\beta} &= q^{-1}L_{1}^{-1}L_{n+1}^{-1}, & K^{(1)}_j &= L_{j+1}^{-1}L_{j}^{-1} \text{ for } j < n \text{ or } j > n.
\end{align*}
\]

It is easy to see that it holds that

\[
\begin{align*}
E^{(1)}_{\beta}F^{(1)}_{\beta} - F^{(1)}_{\beta}E^{(1)}_{\beta} &= \frac{K^{(1)}_{\beta} - (K^{(1)}_{\beta})^{-1}}{q - q^{-1}}, \\
E^{(1)}_jF^{(1)}_j - F^{(1)}_jE^{(1)}_j &= \frac{K^{(1)}_j - (K^{(1)}_j)^{-1}}{q - q^{-1}}.
\end{align*}
\]

The crucial point is the following:

**Lemma 5.12.** The above operators satisfy the $q$-Serre relations for type $A_{2n-1}$. 

*Proof.* This follows easily from Lemma 5.3. \qed

The following is quite obvious:

**Definition/Proposition 5.13.** The element

\[
\Xi_q := L_1 \cdots L_n \cdot L_{n+1}^{-1} \cdots L_{2n}^{-1}
\]

commutes with all the above generators.

The element $\Xi_q$ can be joined to $\mathcal{U}_q(su(n,n)_{\mathbb{C}})$ so that we get $\mathcal{U}_q(u(n,n)_{\mathbb{C}})$. This is useful just as $\mathcal{U}(u(n,n)_{\mathbb{C}})$ was in the classical case.

Having thus given $\psi^{(1)}_q$ on the generators, it is determined on all expressions. We denote by $W^{(1)}_{i,j}$ the image of $W_{i,j}$ (c.f. [2.14]) under the above map and note, in particular, that $\psi^{(1)}_q(W_{1,1}) = F^{(1)}_{\beta}, \psi^{(1)}_q(W_{2,1}) = (-q^{-1})(F^{(1)}_{\beta}F^{(1)}_1 - qF^{(1)}_1F^{(1)}_{\beta}) = F^{(1)}_1F^{(1)}_{\beta} - q^{-1}F^{(1)}_{\beta}F^{(1)}_1 = B_{1}^\dagger B_{n+1}L_{1}$. We will henceforth change the notation as follows: $B_i \rightarrow B_i^{(1)}(1), B_i^\dagger \rightarrow B_i^{\dagger (1)}(1), L_i^{\pm 1} \rightarrow L_i^{\pm 1}(1)$.

Define symbols

\[
\begin{align*}
L_{k-1}^{-1}(1) &= L_1(1) \cdots L_{k-1}(1) \text{ for } k > 1, \quad L_0(1) = 1, \\
L_{n+\ell-1}^{-1}(1) &= L_{n+1}(1) \cdots L_{n+\ell-1}(1) \text{ for } \ell > 1, \quad L_{n+0}^{-1}(1) = 1.
\end{align*}
\]
An easy computation reveals that
\[ W_{k,\ell}^{(1)} = B_{k}^{\dagger}(1)B_{n+\ell}^{\dagger}(1)L_{k-1}\downarrow(1)L_{n+\ell-1}\downarrow(1). \] (5.20)

On the matrix level, we denote the image of the matrix \( W \) by \( W^{(1)} \). The entry of the latter at position \( k, \ell \) is given by \( W_{k,\ell}^{(1)} \). We also proceed to define symbols \( B_{k}^{\dagger}(1) = B_{k}^{\dagger}(1)L_{k-1}\downarrow(1) \)
and notice that
\[ B_{b}^{\dagger}(1)B_{a}^{\dagger}(1) = qB_{a}^{\dagger}(1)B_{b}^{\dagger}(1) \text{ if } n \geq b > a \geq 1 \text{ or } 2n \geq b > a \geq n + 1, \] (5.21)
\[ B_{b}^{\dagger}(1)B_{a}^{\dagger}(1) = B_{a}^{\dagger}(1)B_{b}^{\dagger}(1) \text{ if } n \geq a \geq 1 \text{ and } 2n \geq b \geq n + 1. \] (5.22)

We then have
\[
W^{(1)} = \begin{pmatrix}
B_{1}^{\dagger}(1) & \cdots & B_{n+\ell}^{\dagger}(1) & \cdots & B_{2n}^{\dagger}(1) \\
\vdots & & \vdots & & \vdots \\
B_{k}^{\dagger}(1) & & B_{k}^{\dagger}(1) & & B_{k}^{\dagger}(1) \\
\vdots & & \vdots & & \vdots \\
B_{n}^{\dagger}(1) & & B_{n}^{\dagger}(1) & & B_{n}^{\dagger}(1)
\end{pmatrix} \cdot (B_{n+1}^{\dagger}(1) \cdots B_{n+\ell}^{\dagger}(1) \cdots B_{2n}^{\dagger}(1)) . \] (5.23)

**Proposition 5.14.** The elements \( W_{i,j}^{(1)} \) satisfy the \( \text{FRT} (q^{-1}) \) relations (2.12). In addition: Let \( a < c \) and \( b < d \) be arbitrary. The \( 2 \times 2 \)-minor \( W_{a,b}^{(1)} W_{c,d}^{(1)} - q^{-1} W_{a,d}^{(1)} W_{b,c}^{(1)} \) vanishes and, indeed, in this situation \( W_{a,b}^{(1)} W_{c,d}^{(1)} = q^{-2} W_{a,b}^{(1)} W_{c,d}^{(1)} \).

**Proof.** It suffices to take \( a = b = 1 \) and \( c = d = 2 \). In this case, by inserting the definitions and using the relations, one gets
\[ W_{a,b}^{(1)} W_{c,d}^{(1)} - q^{-1} W_{a,d}^{(1)} W_{b,c}^{(1)} = B_{1}^{\dagger}B_{n+1}^{\dagger}B_{2}^{\dagger}B_{n+2}^{\dagger}L_{1}L_{n+1} - q^{-1} B_{2}^{\dagger}B_{n+1}^{\dagger}L_{1}B_{1}^{\dagger}B_{n+1}^{\dagger}L_{n+1} = 0. \] (5.24)

The other claims follow analogously. \( \square \)

In analogy with Proposition 3.17 and Theorem 3.18 we define \( \mathcal{I}_{2 \times 2}^{(q)} \) to be the ideal in \( \mathcal{A}_{q}^{-} \) generated by all quantum \( 2 \times 2 \) minors, and we define \( (\mathcal{A}_{q}^{-})^{(1)} \) to be the subalgebra of \( \mathcal{HW}_{2n} \) generated by the elements \( w_{i,j}^{(1)} \).

In the same way we get:

**Proposition 5.15.**
\[ (\mathcal{A}_{q}^{-})/\mathcal{I}_{2 \times 2}^{(q)} \equiv (\mathcal{A}_{q}^{-})^{(1)}. \] (5.25)

**Theorem 5.16.** \( \mathcal{I}_{2 \times 2}^{(q)} \) is prime.

Analogously to Proposition 4.3 one gets the following special case of the of coming (§6) general cases:
Proposition 5.17. The cyclic module for $\mathcal{U}_q(su(n,n)^C)$ defined by $v^{(q)}_{2n}$ through $\pi_{2n}^{suN} \circ \psi_{q}^{(1)}$, is an irreducible highest weight representation of $\mathcal{U}_q(su(n,n))$ of highest weight $(0,0,-1)$.

Remark 5.18. This was studied from another perspective by D. Shklyarov, S. Sinel’shchikov, A. Stolin, and L. Vaksman ([42]).

5.2. $q$-analogues of maps and tensor structures. We wish to generalize the maps and results from §3. For any integer $r > 1$ we identify

$$\mathcal{HW}_{2nr} = \mathcal{HW}_{2n} \otimes \cdots \otimes \mathcal{HW}_{2n}.$$ (5.26)

Specifically, we write the generators of $\mathcal{HW}_{2nr}$ as $B_s(k), B_s^\dagger(k)$, $s = 1, \ldots, n$ and $k = 1, \ldots, r$. More generally, for a fixed $k = 1, \ldots, r$, we write an element $G$ in the subalgebra generated by the elements $B_s(k), B_s^\dagger(k), s = 1, \ldots, 2n$ as $G(k)$. The identification in (5.26) is then generated by the identifications

$$G(k) \leftrightarrow 1 \otimes \cdots 1 \otimes G(k) \otimes 1 \otimes \cdots \otimes 1 \text{ (in the kth position)}. \quad (5.27)$$

Definition 5.19. We denote by $\mathcal{HW}_{nr}^X$ the subalgebra of $\mathcal{HW}_{2nr}$ generated by elements $B_s(k), (B_s(k))^\dagger$ having a subscript $\ell = 1, 2, \ldots, n$ and $1 \leq k \leq r$. Likewise, $\mathcal{HW}_{nr}^Y$ denotes the subalgebra generated by elements $B_s(k), (B_s(k))^\dagger$ having a subscript $\ell = n + 1, n + 2, \ldots, 2n$ and $1 \leq k \leq r$.

Clearly:

Lemma 5.20.

$$\mathcal{HW}_{nr}^X \otimes \mathcal{HW}_{nr}^Y = \mathcal{HW}_{2nr}. \quad (5.28)$$

We first define a homomorphism $\psi_{q}^{(r+1)}$ of $\mathcal{U}_q(su(n,n)^C)$ into $\mathcal{HW}_{2n(r+1)}$ for $r \in \mathbb{N}$. We do this by using the co-product $\Delta^r$:

$$\Delta^r : \mathcal{U}_q(g^C) \rightarrow \underbrace{\mathcal{U}_q(g^C) \otimes \cdots \otimes \mathcal{U}_q(g^C)}_{r+1}. \quad (5.29)$$

Then,

$$\psi_{q}^{(r+1)} = (\underbrace{\psi_{q}^{(1)} \otimes \cdots \otimes \psi_{q}^{(1)}}_{r+1}) \circ \Delta^r. \quad (5.30)$$

The co-product we use is the one of ([23]), given in its simplest $\mathcal{U}_q(sl(2, \mathbb{C}))$ version for standard generators $e, f, K$ as

$$\Delta e = e \otimes 1 + K \otimes e, \quad (5.31)$$

$$\Delta f = f \otimes K^{-1} + 1 \otimes f, \quad (5.32)$$

$$\Delta K^{\pm 1} = K^{\pm 1} \otimes K^{\pm 1}. \quad (5.33)$$
To make the formulas more simple, we first set $L_{a,b} = L_a(b)$ in all cases. Then we define, for all $x = 1, \ldots, n, n + 1, \ldots, 2n$, and $b = 1, \ldots, r$
\[ L_{a,b^+} = L_a(b + 1) \cdots L_a(r), \quad \text{and} \]
\[ L_{a,b^1} = L_a(b - 1) \cdots L_a(1). \quad (5.34) \]

We extend the definition to any $b \in \mathbb{Z}$ such that $L_{a,b}^1 = 1$ if $b \notin \{1, \ldots, r\}$. In the following, $j \in \{1, \ldots, n - 1, n + 1, \ldots, 2n - 1\}$.

**Definition 5.21.**

\[ e_{(r)}^\beta = - \sum_{i=1}^r q^{-i+1} B_1(i) B_{n+1}(i) L_{1,(i-1)^1} L_{n+1,(i^1)}^{-1}, \quad (5.36) \]
\[ f_{(r)}^\beta = \sum_{i=1}^r q^{r-i} B_1^\dagger(i) B_{n+1}^\dagger(i) L_{1,(i+1)^\dagger} L_{n+1,(i^1)^\dagger}, \quad (5.37) \]
\[ e_{(r)}^j = \sum_{i=1}^r B_{j+1}(i) B_j^\dagger(i) L_{j+1,(i-1)^1} L_{j,(i^1)^1}, \quad (5.38) \]
\[ f_{(r)}^j = \sum_{i=1}^r B_{j}(i) B_{j+1}^\dagger(i) L_{j+1,(i+1)^\dagger} L_{j,(i^1)^\dagger}, \quad (5.39) \]
\[ (K_{(r)}^\beta)^{\pm 1} = K_{\beta}^{\pm 1}(1) \cdots K_{\beta}^{\pm 1}(r), \quad (5.40) \]
\[ (K_{(r)}^{(r)} j)^{\pm 1} = K_{(r)}^{\pm 1}(1) \cdots K_{(r)}^{\pm 1}(r). \quad (5.41) \]

Since $\triangle$ is a homomorphism, we get:

**Proposition 5.22.** The above operators satisfy the $q$-Serre relations.

Analogously to $r = 1$ we get:

**Definition/Proposition 5.23.** The operator

\[ \Xi_{(r)}^q := \Xi_q(1) \cdots \Xi_q(r) \quad (5.42) \]

commutes with all of the above generators.

**Definition 5.24.** The representation

\[ R_{(r)}^q_{\text{harm}} = \pi_{2nr}^q \circ \psi_{(r)}^q \]

is the $(r)$th $q$-Harmonic Representation of $U_q(u(n,n)^\mathbb{C})$ in $\mathcal{F}_{2nr}^q$.
5.3. The structure of \( \psi_q^{(r+1)}(A_q^-) \). We first wish to compute \( \mathbb{W}^{(r+1)} \) for \( r \geq 1 
\)

**Lemma 5.25.** In \( \mathcal{U}_q(g^C) \otimes \mathcal{U}_q(g^C) \) it holds that

\[
\Delta(T_{\mu_k}T_{\mu_{k-1}} \cdots T_{\mu_1}(F_\beta)) = (5.43)
\]

\[
T_{\mu_k}T_{\mu_{k-1}} \cdots T_{\mu_1}(F_\beta) \otimes K^{\beta - \mu_1 - \cdots - \mu_k} + 1 \otimes T_{\mu_k}T_{\mu_{k-1}} \cdots T_{\mu_1}(F_\beta) +
\]

\[
(q^{-1} - q) \sum_{1 \leq a \leq k} T_{\mu_k-a}T_{\mu_{k-a-1}} \cdots (F_\beta) \otimes (T_{\mu_k} \cdots T_{\mu_{k+2-a}}(F_{\mu_{k+1-a}})) K^{\beta - \mu_1 - \cdots - \mu_{k-a}}.
\]

or, equivalently,

\[
\Delta(W_{k+1,1}) = (5.44)
\]

\[
W_{k+1,1} \otimes K^{\beta - \mu_1 - \cdots - \mu_k} + 1 \otimes W_{k+1,1} +
\]

\[
(q^{-1} - q) \sum_{1 \leq a \leq k} W_{k-a+1,1} \otimes (-q^{-1})^a(T_{\mu_k} \cdots T_{\mu_{k+2-a}}(F_{\mu_{k+1-a}})) K^{\beta - \mu_1 - \cdots - \mu_{k-a}}.
\]

**Proof.** We use Lemma 2.1 and (2.16) repeatedly. We also observe that there will be expressions - with \( E \) unspecified - of the form \( E(K^{-\alpha}F_\gamma - qF_\gamma K^{-\alpha}) \) and \( E(F_\gamma K^{-\alpha} - qK^{-\alpha}F_\gamma) \) where \( \langle \alpha, \gamma \rangle = -1 \). The first kind equals \( E(q^{-1} - q)F_\gamma K^{-\alpha} \), the second is zero. The formulas then follow by induction. \( \square \)

We will generally set \( W_{k,\ell}^{(r+1)} = \psi^{(r+1)}(W_{k,\ell}) \) when there is no chance of confusing the subscript on \( W_{k,\ell}^{(r+1)} \) with a power. More generally, using \( \Delta^{r+1} = (\Delta^r \otimes 1)\Delta \), we have:

**Lemma 5.26.**

\[
W_{k+1,1}^{(r+1)} = (5.45)
\]

\[
W_{k+1,1}^{(r)} \otimes K^{\beta - \mu_1 - \cdots - \mu_k} + 1 \otimes W_{k+1,1}^{(r)} +
\]

\[
(q^{-1} - q) \sum_{1 \leq a \leq k} W_{k-a+1,1}^{(r)} \otimes (-q^{-1})^a(T_{\mu_k} \cdots T_{\mu_{k+2-a}}(F_{\mu_{k+1-a}})) K^{\beta - \mu_1 - \cdots - \mu_{k-a}}.
\]

Equivalently, using the notation \( [A, B]_q = AB - q^{-1}BA \),

\[
W_{k+1,1}^{(r+1)} = W_{k+1,1}^{(r)} \otimes K^{\beta - \mu_1 - \cdots - \mu_k}
\]

\[
+ (q^{-1} - q) W_{k,1}^{(r)} \otimes (-q^{-1})F_{\mu_k} K^{\beta - \mu_1 - \cdots - \mu_{k-1}}
\]

\[
+ (q^{-1} - q) W_{k-1,1}^{(r)} \otimes (-q^{-1})[F_{\mu_k}, F_{\mu_{k-1}}]_q K^{\beta - \mu_1 - \cdots - \mu_{k-2}}
\]

\[
+ (q^{-1} - q) W_{k-2,1}^{(r)} \otimes (-q^{-1})[F_{\mu_k}, [F_{\mu_{k-1}}, F_{\mu_{k-2}}]_q]_q K^{\beta - \mu_1 - \cdots - \mu_{k-3}}
\]

\[
+ \cdots
\]

\[
+ (q^{-1} - q) W_{1,1}^{(r)} \otimes (-q^{-1})[[F_{\mu_k}, \ldots F_{\mu_3}, [F_{\mu_2}, F_{\mu_1}]_q]_q \ldots]_q K^{\beta}
\]

\[
+ 1_R \otimes W_{k+1,1}^{(1)}.
\]

**Definition 5.27.**

\[
\forall r = 1, 2, \ldots, \mathbb{W}_{k,\ell}^{(r)} = \psi_q^{(r)}(W_{k,\ell}).
\]

From Definition 5.11, and formula (5.5), we then get:
Lemma 5.28.

\[ W_{k+1,1}^{(r+1)} = W_{k+1,1}^{(r)} \otimes q \left( L_{k+1} L_{n+1} \right) (r + 1) \]
\[ + \left( q^{-1} - q \right) W_{k+1,1}^{(r)} \otimes (-1) \left( B_{k+1}^{\dagger} B_k L_{k+1} L_{n+1} \right) (r + 1) \]
\[ + \left( q^{-1} - q \right) W_{k+1,1}^{(r)} \otimes (-1) \left( B_{k+1}^{\dagger} B_{k-1} L_k L_{k-1} L_{n+1} \right) (r + 1) \]
\[ + \left( q^{-1} - q \right) W_{k+1,1}^{(r)} \otimes (-1) \left( B_{k+1}^{\dagger} B_{k-2} L_k L_{k-2} L_{n+1} \right) (r + 1) \]
\[ + \cdots \]
\[ + \left( q^{-1} - q \right) W_{1,1}^{(r)} \otimes (-1) \left( B_{k+1}^{\dagger} B_1 L_k L_{k-1} \cdots L_2 L_{n+1} \right) (r + 1) \]
\[ + 1_R \otimes W_{k+1,1}^{(1)} (r + 1). \]

Recall that \( W_{k+1,1}^{(1)} (r + 1) = B_{k+1}^{\dagger} B_{n+1}^{\dagger} L_{k+1} \) (at the \((r + 1)\)th position).

More generally,

\[ W_{k+1,\ell+1}^{(r+1)} = W_{k+1,\ell+1}^{(r)} \otimes q \left( L_{k+1} L_{n+\ell+1} \right) (r + 1) \]
\[ + (1 - q^{-2}) \sum_{x=1}^{k} q W_{x,\ell+1}^{(r)} \otimes \left( B_{k+1}^{\dagger} B_x L_k \cdots L_x L_{n+\ell+1} \right) (r + 1) \]
\[ + (1 - q^{-2}) \sum_{y=1}^{k} q W_{k+1,y}^{(r)} \otimes \left( B_{n+\ell+1}^{\dagger} B_{n+y} L_{n+\ell} \cdots L_{n+y} L_{k+1} \right) (r + 1) \]
\[ + (1 - q^{-2}) \sum_{x,y=1}^{k,\ell} q W_{x,y}^{(r)} \otimes \left( B_{k+1}^{\dagger} B_{n+\ell+1} B_x B_{n+y} L_{n+\ell} \cdots L_{n+y} L_k \cdots L_x \right) (r + 1) \]
\[ + 1_R \otimes W_{k+1,\ell+1}^{(1)} (r + 1). \]

Definition 5.29. In \( \mathcal{HW}_{2nr} \), for \( k = 1, \cdots, r - 1 \), set

\[ B_{k}^{\dagger}(k, r) = B_{k}^{\dagger}(k) L_{(\ell-1)}(k) L_{\ell}(k + 1) \cdots L_{\ell}(r), \]
\[ B_{\ell}(k, r) = B_{\ell}(k) L_{(\ell-1)}^{-1}(k) L_{\ell}^{-1}(k + 1) \cdots L_{\ell}^{-1}(r), \]
\[ B_{n+\ell}^{\dagger}(k, r) = B_{n+\ell}(k) L_{n+\ell-1}(k) L_{n+\ell}(k + 1) \cdots L_{\ell}(r), \]
\[ B_{n+\ell}(k, r) = B_{n+\ell}(k) L_{n+\ell-1}(k) L_{n+\ell-1}(k + 1) \cdots L_{n+\ell-1}(r). \]

Moreover, \( B_{k}^{\dagger}(r) = B_{k}^{\dagger}(r, r) \) := \( B_{k}^{\dagger}(r) L_{(\ell-1)}(k) \) and \( B_{\ell}(r) = B_{\ell}(r, r) := B_{\ell}(r) L_{(\ell-1)}^{-1}(k), \) for any \( x, y \in \{1, \ldots, 2n\} \), respectively.
Definition 5.30. Two operators $A, B$ quasi-commute if $AB - q^\alpha BA = 0$ for some $q^\alpha$. If the generators of an algebra all quasi-commute we say that the algebra is a quasi-polynomial algebra.

The following is straightforward:

**Lemma 5.31.** The elements in Definition 5.29 quasi-commute with the following notable exception:

$$\forall k, \ell : \mathbb{B}_\ell(k, r)\mathbb{B}^\dagger_\ell(k, r) - q^{-2}\mathbb{B}^\dagger_\ell(k, r)\mathbb{B}_\ell(k, r) = q^{-1} \cdot I. \quad (5.52)$$

Then, obviously:

**Proposition 5.32.** The elements in Definition 5.29 generate an algebra which has a PBW-like basis.

**Corollary 5.33.**

$$\mathcal{W}_{k+1, \ell+1}(r) = \mathcal{W}_{k+1, \ell+1}(r) qL_{k+1}(r)L_{n+\ell+1}(r)$$

$$+ (1 - q^{-2}) \sum_{x=1}^{k} q\mathcal{W}_{x, \ell+1}(r) L_x(r)L_{n+\ell+1}(r)\mathbb{B}^\dagger_{k+1}(r, r)\mathbb{B}_x(r, r)$$

$$+ (1 - q^{-2}) \sum_{y=1}^{\ell} q\mathcal{W}_{k+1, y}(r) L_{k+1}(r)L_{n+y}(r)\mathbb{B}^\dagger_{n+\ell+1}(r, r)\mathbb{B}_{n+y}(r, r)$$

$$+ (1 - q^{-2})^2 \sum_{x,y=1}^{k,\ell} q\mathcal{W}_{x,y}(r) L_x(r)L_{n+y}(r)\mathbb{B}^\dagger_{k+1}(r, r)\mathbb{B}^\dagger_{n+\ell+1}(r, r)\mathbb{B}_x(r, r)\mathbb{B}_{n+y}(r, r)$$

$$+ \mathbb{B}^\dagger_{k+1}(r, r)\mathbb{B}^\dagger_{n+\ell+1}(r, r).$$

**Definition 5.34.** We denote by $\mathcal{H}\mathcal{W}_{Z_{2nr}}^Z$ the subalgebra generated by the elements in Definition 5.29. Furthermore, $\mathcal{H}\mathcal{W}_{X_{nr}}^X$ denotes the subalgebra generated by those of the above generators having a subscript $\ell = 1, 2, \ldots, n$ and $\mathcal{H}\mathcal{W}_{Y_{nr}}^Y$ denotes the subalgebra generated by those of the above generators having a subscript $n + \ell = n + 1, n + 2, \ldots, 2n$.

Clearly:

**Lemma 5.35.** There is a PBW basis for $\mathcal{W}_{2nr}^Z \cdot v_{2nr}^{(q)}$ of the form

$$\left(\mathbb{B}^\dagger_1(1, r)\right)^{a_{1,1}} \left(\mathbb{B}^\dagger_2(1, r)\right)^{a_{2,1}} \cdots \left(\mathbb{B}^\dagger_{2n}(r, r)\right)^{a_{2n,r}} \cdot v_{2nr}^{(q)}. \quad (5.54)$$

The following result is easy to see:

**Lemma 5.36.** $\mathcal{H}\mathcal{W}_{X_{nr}}^X$ and $\mathcal{H}\mathcal{W}_{Y_{nr}}^Y$ commute and

$$\mathcal{H}\mathcal{W}_{X_{nr}}^X \otimes \mathcal{H}\mathcal{W}_{Y_{nr}}^Y = \mathcal{H}\mathcal{W}_{Z_{2nr}}^Z. \quad (5.55)$$
Then, by (5.53), it follows directly that

Let us introduce two diagonal matrices

Proof:

\[ \Lambda(k, r) := q^{1/2} \sum_{a \geq b} \left( \delta_{a,b} + (1 - \delta_{a,b})(1 - q^{-2})B^\dagger_a(k, r)B_b(k, r) \right) E_{a,b}, \quad (5.56) \]

\[ \mathcal{C}(k, r) := q^{1/2} \sum_{d \geq c} \left( \delta_{c,d} + (1 - \delta_{c,d})(1 - q^{-2})B^\dagger_{n+d}(k, r)B_{n+c}(k, r) \right) E_{c,d}, \quad (5.57) \]

\[ \mathcal{X}^0(k, r) := \begin{pmatrix} B^\dagger_1(k, r) \\ \vdots \\ B^\dagger_n(k, r) \end{pmatrix}, \quad \mathcal{Y}^0(k, r) := \begin{pmatrix} B^\dagger_{n+1}(k, r) \\ \vdots \\ B^\dagger_{2n}(k, r) \end{pmatrix}, \quad (5.58) \]

\[ \mathcal{W}^0(k, r) := \mathcal{X}^0(k, r) \cdot \mathcal{Y}^0(k, r)^T. \quad (5.59) \]

Analogously to Proposition 5.14, and with a similar proof, we have:

**Proposition 5.38.** Let \( \mathcal{W}^0_{i,j}(k, r), i, j = 1, \ldots, n \) denote the entries of \( \mathcal{W}^0(k, r) \), \( k = 1, \ldots, r \). For a fixed, arbitrary \( k \), these elements satisfy the FRT(\( q^{-1} \)) relations (2.12). In addition: Let a < c and b < d be arbitrary. The \( 2 \times 2 \) \( q \)-minor \( \mathcal{W}^0_{a,b}(k, r)\mathcal{W}^0_{c,d}(k, r) - q^{-1}\mathcal{W}^0_{a,d}(k, r)\mathcal{W}^0_{c,b}(k, r) \) vanishes and, indeed, in this situation \( \mathcal{W}^0_{a,b}(k, r)\mathcal{W}^0_{c,d}(k, r) = q^{-2}\mathcal{W}^0_{c,b}(k, r)\mathcal{W}^0_{a,d}(k, r) \).

We let \( \mathcal{HW}^0_{2nr} \) denote the subalgebra of \( \mathcal{HW}^0_{2nr} \) generated by the entries of \( \mathcal{W}^0(k, r) \), \( k = 1, \ldots, r \). Likewise, \( \mathcal{HW}^0_{nr} \) denotes the subalgebra generated by the entries of \( \mathcal{X}^0(k, r) \) \( k = 1, \ldots, r \), and \( \mathcal{HW}^0_{nr} \) denotes the subalgebra generated by the entries of \( \mathcal{Y}^0(k, r) \), \( k = 1, \ldots, r \).

The following is obvious:

**Lemma 5.39.** \( \mathcal{HW}^0_{2nr} \) is a quasi-polynomial algebra. We have

\[ \mathcal{HW}^0_{2nr} = \mathcal{HW}^0_{nr} \otimes \mathcal{HW}^0_{nr}. \quad (5.60) \]

**Proposition 5.40.**

\[ \mathcal{W}^{(r)} = \mathcal{W}^0(r, r) + \sum_{k=2}^r \Lambda(k, r) \cdots \Lambda(k, r) \mathcal{W}^0(k - 1, r) \mathcal{C}(k, r) \cdots \mathcal{C}(r, r). \quad (5.61) \]

**Proof:** Let us introduce two diagonal \( n \times n \) matrices

\[ \mathbb{L}^\dagger(r) = \text{Diag}(L_1(r), \ldots, L_n(r)) \] and \( \mathbb{L}^\dagger(r) = \text{Diag}(L_{n+1}(r), \ldots, L_{2n}(r)). \quad (5.62) \]

Then, by (5.53), it follows directly that

\[ \mathcal{W}^{(r)} = \mathcal{W}^0(r, r) + \Lambda(r, r)\mathbb{L}^\dagger(r)\mathcal{W}^{(r-1)}\mathbb{L}^\dagger(r)\mathcal{C}(r, r). \quad (5.63) \]
Proceeding recursively, one obtains the result if one makes the following two observations: 1)
\[ \mathbb{L}^\dagger(r) \cdots \mathbb{L}^\dagger(r-k) A(r-k-1, r-k-1)(\mathbb{L}^\dagger(r) \cdots \mathbb{L}^\dagger(r-k))^{-1} = A(r-k-1, r), \quad (5.64) \]
with a similar statement for \( C(r-k-1, r) \).

2)
\[ \mathbb{L}^\dagger(r) \cdots \mathbb{L}^\dagger(r-k) \mathcal{W}(r-k-1, r-k-1) \mathbb{L}^\dagger(r-k) \cdots \mathbb{L}^\dagger(r)) = \mathcal{W}(r-k-1, r). \quad (5.65) \]

Corollary 5.41. The entries of \( \mathcal{W}(r) \) are elements of \( \mathcal{H} \mathcal{W}_{2nr}^\mathbb{Z} \).

Definition 5.42. Set \( X_r(r) = X(r, r) \), \( Y_r(r) = Y(r, r) \), and, for \( k = 1, \ldots, r-1 \),
\[ X_r(k) := A(r, r) \cdots A(k+1, r) X^0(k, r), \quad Y_r(k) := C^T(r, r) \cdots C^T(k+1, r) Y^0(k, r). \quad (5.66) \]

We easily get the following two assertions (compare to (3.34)):

Proposition 5.43.
\[ \mathcal{W}(r) = X_r(r) Y^T_r(r) + X_r(k) Y^T_r(k) + \cdots + X_r(1) Y^T_r(1). \quad (5.67) \]

Corollary 5.44. Let \( X_r \) be the \( n \times r \) matrix whose \( k \)th column is \( X_r(k) \) and let \( Y_r \) be the \( n \times r \) matrix whose \( k \)th column is \( Y_r(k) \). Then
\[ \mathcal{W}(r) = X_r Y^T_r. \quad (5.68) \]

Notice that the bases depend on \( r \).

Two more easy consequences are:

Corollary 5.45.
\[ \mathcal{H} \mathcal{W}_{2nr}^\mathbb{Z} \cdot v_{2nr} = \mathcal{H} \mathcal{W}_{2nr}^{\mathbb{Z},0} \cdot v_{2nr}. \quad (5.69) \]

Corollary 5.46. The image \( \mathcal{H} \mathcal{W}_{2nr}^{\mathbb{A}^+} \) of \( \mathbb{A}^- \) in \( \mathcal{H} \mathcal{W}_{2nr} \) by \( \psi^{(r)}_q \) is generated by the entries of \( \mathcal{W}^{(r)} \).

5.4. Annihilators.

Definition 5.47. We use the definition of a quantum minor in \( \mathbb{A}^- \) as given in (2.17) with \( a = q^{-1} \). We let \( \mathcal{I}^{(q)}_{k \times k} \) denote the ideal in \( \mathbb{A}^- \) generated by all quantum \( k \times k \) minors.

Definition 5.48. \( Ann_{q}^{0}(2nr) \) denotes the set of elements in \( \mathbb{A}^- \) that annihilate \( v_{2nr}^{(q)} \) in the representation \( \mathcal{R}^{\text{harm}}_r \).
It is easy to see that this is a $\mathcal{U}_q(\mathfrak{g})$-module which is a left ideal.

Using the quantum Laplace expansions (see e.g. [34]), the following is not hard to prove:

**Proposition 5.49.** The left ideal generated by $k \times k$ quantum minors is equal to the right ideal generated by $k \times k$ quantum minors.

We have:

**Proposition 5.50.**

$$I^{(q)}_{(r+1)\times(r+1)} \subseteq \text{Ann}_q^{-1}(2nr).$$

(5.70)

**Proof:** This follows by the representation theory of $\mathcal{U}_q(\mathfrak{g})$. The action of $\mathcal{U}_q(\mathfrak{g})$ on $R^{wharm}_r(I^{(q)}_{(r+1)\times(r+1)}) \cdot v^{(q)}_{2nr}$ is just the restriction of the left action on $F^{(q)}_{2nr}$. The latter is the $r$th fold tensor product of the symmetric representation and hence cannot accommodate more that $r \times r$ minors corresponding to anti-symmetric $r$ tensors. See also Proposition 6.1. □

**Definition 5.51.** Let $W^{(r,0)}$ denote the $n \times n$ matrix

$$W^{(r,0)} = \sum_{k=1}^R W^0(k, r).$$

(5.71)

Specifically, the entries are given as

$$W_{ij}^{(r,0)} = \sum_{k=1}^r B^i_0(k, r)B^j_{n+j}(k, r) \in \mathcal{H}W^{Z,0}_{2nr}. $$

(5.72)

$W^{(r,0)}$ is the associated quasi-polynomial matrix at level $r$.

We shall see that for many purposes, the associated quasi-polynomial matrix at level $r$ contains enough information to reach conclusions about $W^{(r)}$.

Similar to Corollary 5.44 we have:

**Corollary 5.52.** Let $X^0_r$ be the $n \times r$ matrix whose $k$th column is $X^0(k, r)$ and let $Y^0_r$ be the $n \times r$ matrix whose $k$th column is $Y^0(k, r)$. Then

$$W^{(r,0)} = X^0_r(Y^0_r)^T. $$

(5.73)

We now discuss $\ell \times \ell$ quantum determinants involving the entries of $W^{(r,0)}$. The algebra $\mathcal{H}W^{Z,0}_{2nr}$ does not satisfy the FRT equations. Non-the-less, we apply (2.18) to it. For simplicity we only give the top left “determinant”, which we mark by “TL”. (The formula (2.17) will actually give the same result.)

**Lemma 5.53.**

$$ (\det_q)_{\ell \times \ell}^{TL}(W^{(r,0)}) = $$

$$\sum_{\sigma \in S_\ell} (-q)^{-\ell(\sigma)} \sum_{r_1, r_2, \ldots, r_\ell} B^i_{n+1}(k_1)B^j_{\sigma(1)} B^i_{n+2}(k_2)B^j_{\sigma(2)} \cdots B^i_{n+\ell}(k_\ell)B^j_{\sigma(\ell)} = $$

$$\sum_{k_1, k_2, \ldots, k_\ell} (B^i_{n+1}(k_1) \cdots B^i_{n+\ell}(k_\ell)) \sum_{\sigma \in S_\ell} (-q)^{-\ell(\sigma)} B^i_{\sigma(1)}(k_1) \cdots B^i_{\sigma(\ell)}(k_\ell).$$

(5.74)
If we then consider the case \( \ell > r \) (still, \( \ell \leq n \)) then, in the expressions
\[
\sum_{\sigma \in S_\ell} (-q)^{-\ell(\sigma)}(B_{\sigma(1)}^\dagger(k_1)B_{\sigma(2)}^\dagger(k_2) \cdots B_{\sigma(\ell)}^\dagger(k_\ell)),
\] (5.75)
one must have \( k_i = k_j \) for at least one pair \((i, j)\) with \( i \neq j \).

**Lemma 5.54.** Suppose that \( k_{i_0} = k_{j_0} \) with \( i_0 < j_0 \). We may assume that no \( k_i \), \( i_0 < i < j_0 \) is equal to \( k_{i_0} \). Then
\[
\sum_{\sigma \in S_\ell} (-q)^{-\ell(\sigma)}B_{\sigma(1)}^\dagger(k_1)B_{\sigma(2)}^\dagger(k_2) \cdots B_{\sigma(\ell)}^\dagger(k_\ell) = 0.
\] (5.76)

**Proof:** Let \( k_{i_0} = k_{j_0} = a \in \mathbb{N} \). It is easy to see that \( B_i^\dagger(k) \) commutes with \( B_j^\dagger(\ell) \) if \( (i - j)(k - \ell) \neq 0 \). We focus on the terms \( B_{\sigma(i_0)}^\dagger(a)B_{\sigma(j_0)}^\dagger(b) \) as \( \sigma \) varies through \( S_\ell \).

For any choice of values of \( \sigma \) on all positions \( i \neq i_0, j_0 \) there are exactly two possible choices of \( (\sigma(i_0), \sigma(j_0)) \), which we may denote as \((c, d)\) and \((d, c)\) with \( c < d \). The last one is a “cross-over” and has a length which is one more than the length of the other. But \( B_d^\dagger(a)B_c^\dagger(a) = qB_c^\dagger(a)B_d^\dagger(a) \) (Definition [5.29] and (5.4)). Thus, the two expressions cancel.

We then conclude:

**Corollary 5.55.** Any \((r + 1) \times (r + 1)\) minor of \( \mathbb{W}^{(r, 0)} \) is zero. \((r + 1 \leq n)\)

We now offer a technical computation to be used below:

**Lemma 5.56.** Assume \( i > x \) and \( j > y \). Then
\[
\left(B_i^\dagger(r)B_x^\dagger(r)\mathbb{W}^{(r-1)}_{x,j} + B_{n+j}^\dagger(r)B_{n+y}(r)\mathbb{W}^{(r-1)}_{i,y} + B_i^\dagger(r)B_{n+j}^\dagger(r)B_x^\dagger(r)B_{n+y}(r)\mathbb{W}^{(r-1)}_{x,y}\right) \cdot \left(B_{a+1}^\dagger(r)B_{n+x}^\dagger(r)B_c^\dagger(r)B_{n+y}(r)\mathbb{W}^{(r-1)}_{x,y}\right) = q^{-1}\delta_{x,x}B_i^\dagger(r)B_{n+b}^\dagger(r)\mathbb{W}^{(r-1)}_{a,x} + q^{-1}\delta_{x,y}B_{n+j}^\dagger(r)B^\dagger(r)B_{n+j}^\dagger(r)\mathbb{W}^{(r-1)}_{x,y} + q^{-1}\delta_{y,x}B_{n+d}(r)B_{n+d}(r)\mathbb{W}^{(r-1)}_{c,y} + q^{-1}\delta_{y,y}B_{n+j}(r)B_{n+j}(r)\mathbb{W}^{(r-1)}_{x,y} + q^{-2}\delta_{x,x}B_i^\dagger(r)B_{n+j}(r)\mathbb{W}^{(r-1)}_{x,y} + q^{-2}\delta_{x,y}B_{n+j}(r)\mathbb{W}^{(r-1)}_{x,y}.
\]

**Proof:** Using Lemma [5.31] and the fact that all \( B_a(r) \) commute with all \( \mathbb{W}^{(r-1)}_{b,c} \), this is a straightforward computation.

Now recall Corollary [5.33]. By paying attention to degrees and observing everywhere that
\[
B_i^\dagger(r)B_{n+j}^\dagger(r) = \mathbb{W}^{(r-0)}_{i,j} - \mathbb{W}^{(r-1,0)}_{i,j}
\] (5.77)
we obtain, by applying the last lemma repeatedly:

**Lemma 5.57.** There exist, depending on the choices, homogeneous polynomials \( p_i^{(r,0)} \) of degree \( s \) in the entries of \( \mathbb{W}^{(r,0)} \) and polynomials \( \hat{p}_i^{(r-1)} \) in the entries of \( \mathbb{W}^{(r-1,0)} \)
and $W^{(r-1)}$ such that, when $k \geq 2$ (in the case $k = 1$ the second term is 0)

$$W^{(r)}_{i_1,j_1} \cdots W^{(r)}_{i_k,j_k} v_{2nr} = W^{(r,0)}_{i_1,j_1} \cdots W^{(r,0)}_{i_k,j_k} v_{2nr} + \sum_{s=1}^{k-1} p_s^{(r,0)} \cdot \hat{p}_s^{(r-1)} v^{(q)}_{2nr}.$$

**Remark 5.58.** Using Corollary 5.55 the above Lemma offers an alternative proof of Proposition 5.50. On e.g. the level of $U_q(\mathfrak{g}^C)$ modules, we may filter the $R$th fold tensor product - construed as a series of $R$ tensor products from, say, the left, by the previous $(r-1)$th tensor product. Indeed, we may (compare to the discussions about tensor products in Section 4) pass to the quotient by the left ideal generated by the elements $(W^{(r-1)}_{i,j}) v_{2nr}^q$ - i.e we can set them equal to zero. Finally, we can apply Corollary 5.55.

Let $M_{top}(r)$ denote the top leftmost $r \times r$ minor of $W^{(r)}$.

**Corollary 5.59.** $(M_{top}(r)) v_{2nr}^q$ is non-zero.

**Proof:** It suffices to prove that the analogous element obtained from $W^{(r,0)}$ is non-zero. Consider the, obviously non-zero, element $\prod_{i=1}^{r} B_i^{\dagger}(i,r) B_{n+i}^{\dagger}(i,r)$. This is a summand in (5.75) precisely when $\forall i : k_i = i$ and $\sigma = Id$. □

**Corollary 5.60.** $(M_{top}(r))^k v_{2nr}^q$ is non-zero for any $k \in \mathbb{N}$.

**Proof:** This follows similarly. □

More generally, let $X_i(r)$ to be the $i \times i$ minor of $W^{(r)}$ consisting of the first $i$ rows and columns.

**Corollary 5.61.** The element $\prod_{i=1}^{r} X_i^{N_i} v_{2nr}^q$ is non-zero for any $(N_1, \cdots, N_r) \in \mathbb{N}_0^r$.

**Proof:** If any such vector were to belong to the left ideal $Ann_q^{-,0}(2nr)$ a simple tensor product argument reveals that $(M_{top}^r)^k \in Ann_q^{-,0}(2nr)$ for some $k \in \mathbb{N}$ which contradicts the previous corollary. □

The above elements are highest weight vectors for $U_q(\mathfrak{u}(n) \times \mathfrak{u}(n))$ (c.f Proposition 6.3). In the language of Young diagrams (here: double diagrams), we get exactly those that have at most $r$ rows. In the ideal $\mathcal{I}_{(r+1) \times (r+1)}^{(q)}$ all $U_q(\mathfrak{u}(n) \times \mathfrak{u}(n))$ types will necessarily have Young diagrams with at least $(r+1)$ rows. Thus we conclude:

**Theorem 5.62.**

$$Ann_q^{-,0}(2nr) = \mathcal{I}_{(r+1) \times (r+1)}^{(q)}.$$
5.5. $q$-prime. We now turn our attention to prime ideals.

Lemma 5.63. Let $p \in \mathcal{H} \mathcal{W}_{2nr}^q$, let $L = L_k(\ell)$ for some fixed $k, \ell$, and let

$$p = \sum_{i=1}^{N} p_i, \text{ where } \forall i : Lp_iL^{-1} = q^{n_i}p_i. \quad (5.78)$$

Suppose the elements $n_1, \cdots, n_N \in \mathbb{N}_0$ are pairwise different. Suppose that $pv_{2nr}^{(q)} = 0$. Then

$$\forall i = 1, \cdots, N : \ p_i v_{2nr}^{(q)} = 0. \quad (5.79)$$

Proof: We have that for all $s \in \mathbb{N}_0$: $L^s p v_{2nr}^{(q)} = 0$. Hence

$$\forall s \in \mathbb{N}_0 : \ \sum_{i=1}^{N} q^{sn_i}p_i v_{2nr}^{(q)} = 0. \quad (5.80)$$

The claim follows easily by subtractions and multiplications by $q$. See also Artin’s Theorem on linear independence of characters ([1]). □

Theorem 5.64 (Q-Prime). The $q$-determinantal ideals are prime.

Proof. Set $W = W^{(r)}$ (recall that they satisfy the FRT$(q^{-1})$ equations). Further, set

$$a = (a_{n,1}, a_{n,2}, \cdots, a_{n,n}), \quad (5.81)$$

$$b = (b_{1,1}, \cdots, b_{i,j}, \cdots, b_{n-1,n}), \quad i \leq n - 1, \quad (5.82)$$

$$p = \sum_{a,b} \alpha_{a,b} W^b W^a, \quad \text{and} \quad (5.83)$$

$$\hat{p} = \sum_{c,d} \beta_{c,d} W^d W^c \ (c, d \text{ defined analogously}). \quad (5.84)$$

Assume $(p \cdot \hat{p}) v_{2nr}^{(q)} = 0$. Then either $pv_{2nr} = 0$ or $\hat{p}v_{2nr}^{(q)} = 0$.

Proof. The elements $p, \hat{p} \in A_q^-$ are only determined modulo $T^{(q)}_{(r+1) \times (r+1)}$. We will use this fact to make some assumptions about them.

We order the elements $a, c$ lexicographical so that $(n, n)$ is the biggest index and $W_{n,n}$ is placed furthest to the right. Let $a_0$ be the biggest power in $a$, and $c_0$ defined analogously. The elements $b, d$ are ordered similarly, row by row, ending with the first row at the left. We use a PBW basis based on this order.

$$p = \sum_{a,b} \alpha_{a_0,b} W^b W^{a_0} + \text{L.o.t.s and, similarly} \quad (5.85)$$

$$\hat{p} = \sum_{c,d} \beta_{c_0,d} W^d W^{c_0} + \text{L.o.t.s}. \quad (5.86)$$

The symbol L.o.t.s in both equations stand for lower order terms.

Observe that $W^a W^b = W^b W^a$ modulo lower order terms.

Consider then
\[
(\sum \alpha_{ao,b}W^b) \cdot (\sum \beta_{c0,d}W^d)W^{a_0}W^{c_0}v_{2nr}^{(q)} = p_0 \cdot \hat{p} \cdot W^{a_0}W^{c_0}v_{2nr}^{(q)},
\]
where \(p_0 = \sum \alpha_{ao,b}W^b\) and \(\hat{p}_0 = \sum \beta_{c0,d}W^d\).

The assumptions we make is that \(p_0 \cdot v_{2nr}^{(q)} \neq 0\) and \(\hat{p}_0 \cdot v_{2nr}^{(q)} \neq 0\). Indeed, if e.g. \(p_0 \cdot v_{2nr}^{(q)} = 0\) then \(p_0 \in I_{R+1}^q\) and the latter is a 2-sided ideal by Proposition 5.49, hence \(p_0W^{a_0}\) can be left out of our considerations.

By construction, \(B^+(k, r)\) and \(B^+_2(k, r)\) do not take part in \(p_0, \hat{p}_0\) for any \(k = 1, \ldots, r\). Similarly, \(B_n(k, r)\) and \(B^+_2(k, r)\) do not take part in \(p_0, \hat{p}_0\) for any \(k = 1, \ldots, r\). Indeed, by Corollary 5.33, not even in \(p, \hat{p}\).

Let us first look at \((W^{(r)}_{nn})^N v_{2nr}^{(q)}\). The key ingredient is (5.53), or its equivalent form (5.61). Observe that no operators \(B_n(k, r)\) or \(B^+_2(k, r)\) take part in \(W^{(r)}_{nn}\), and that if a term \(B_i(k, r)\) is present, then \(i \neq n, 2n\) and hence may be moved to the right where it eventually will annihilate \(v_{2nr}^{(q)}\). We then get that
\[
(W^{(r)}_{nn})^N v_{2nr}^{(q)} = \left(B^+_1(1, r)B^+_2(1, r) + \cdots + B^+_n(r, r)B^+_2n(r, r)\right)^N v_{2nr}^{(q)}.
\]
More generally, in the \(n\)th row at column \(j\) we only get annihilation operators \(B_y(k, r)\) with \(y < j\), and \(B_x(k, r)\) with \(x < n\), hence, by our choice of ordering, we get
\[
(W^{(r)}_{nn})^{a_{n1}}W^{a_{n2}} \cdots W^{a_{nn}}v_{2nr}^{(q)} = \left(B^+_1(1, r)B^+_2n(1, r) + \cdots + B^+_n(r, r)B^+_2n(r, r)\right)^{a_{n1}} \left(B^+_1(1, r)B^+_2(n+2)(1, r) + \cdots + B^+_n(r, r)B^+_2(n+2)(r, r)\right)^{a_{n2}} \cdots \left(B^+_1(1, r)B^+_2n(1, r) + \cdots + B^+_n(r, r)B^+_2n(r, r)\right)^{a_{nn}} v_{2nr}^{(q)} = (W^{(r0)}_{n1})^{a_{n1}} (W^{(r0)}_{n2})^{a_{n2}} \cdots (W^{(r0)}_{nn})^{a_{nn}} v_{2nr}^{(q)}.
\]

Let us now look at \(L_n(1)\) and \(L_{2n}(1)\) weights:
The we have that
\[
L_n(1)^k(p \cdot \hat{p})L_n(1)^{-k}v_{2nr}^{(q)} = 0,
\]
hence, by Lemma 5.63, any weight space is zero.

It follows that \(p_0 \cdot \hat{p}_0\) annihilates for instance
\[
(B^+_n(1, r))^{a_{n1}+a_{n2}+\cdots+a_{nn}}(B^+_n(1, r))^{a_{n1}}(B^+_n+2(1, r))^{a_{n2}} \cdots (B^+_2n(1, r))^{a_{nn}} v_{2nr}^{(q)}.
\]
We rewrite \(p_0 \cdot \hat{p}_0\) in such a way that the terms \(B_x(k, r)\) move to the right. At the same time we now write it in terms of the variables \(B^+_x(k, r)\) and \(B_y(k, r)\), \(x, y = 1, \ldots, 2n\) but with the aforementioned exceptions.

Observe, by e.g. proposition 5.67, that \(p_0 \cdot \hat{p}_0\) contains no elements of the form \(B_x(1, r), x = 1, \ldots, 2n\). Furthermore, any \(B_x(k, r), x = 1, \ldots, 2n, \) and \(k = 2, \ldots, R\) annihilate the element in (5.94) automatically. Suppose then that \(p_0 \cdot \hat{p}_0\) contains a
biggest non-trivial summand \( h \in \mathcal{H}W_{2nr}^Z \) and that \( h \cdot v^0_{2nr} \neq 0 \). C.f. Corollary 5.41

Clearly then, by Lemma 5.35, also

\[
h \cdot (\mathbb{B}_n(1, r))^{a_{n,1}+a_{n,2}+\cdots+a_{n,n}}(\mathbb{B}_n+1(1, r))^{a_{n,1}}(\mathbb{B}_{n+2}(1, r))^{a_{n,2}}\cdots(\mathbb{B}_{2n}(1, r))^{a_{n,n}} \cdot v^0_{2nr} \neq 0. 
\]

(5.95)

This is a contradiction, so, in conclusion, it follows that \( p_0 \cdot \hat{p}_0 v^0_{2nr} = 0 \). As mentioned, \( p_0 v^0_{2nr} \neq 0 \) and \( \hat{p}_0 v^0_{2nr} \neq 0 \).

We thus arrive at a similar situation, but where the \( n \)th row of \( \mathbb{W}^{(r)} \) has been removed.

Now remove the last column \((i, j) = (i, n)\) by a similar argument.

Suppose first that \( n = r + 1 \) so that we are looking at the quotient module by the ideal generated by the \((r + 1) \times (r + 1)\) quantum determinant. Here we observe that a non-zero polynomial in the variables \( W_{ij} \) with \( \max\{i, j\} \leq n - 1 \) can never be a product of a polynomial and the \( n \times n \) quantum determinant. Neither can the product of two such because the mentioned condition defines a sub-algebra. So if \( n = r + 1 \) we reach a contradiction.

Of course, we always have that \( n \geq r + 1 \). If \( n = r + k \), with \( k > 1 \) we can by the previous arguments make the reduction \((p, \hat{p}) \rightarrow (p_0, \hat{p}_0) \rightarrow \cdots \) until we reach a pair \( p_{k-1}, \hat{p}_{k-1} \) which depend only on the top \( r = n - k \) variables. But we cannot get an \( r + 1 \) determinant from such variables, so by Theorem 5.62 we cannot get zero. This contradiction then proves the general theorem.

\[\Box\]

6. The full decomposition of the \( q \)-Fock spaces

The \( q \)-Stone–von Neumann module \( F^{(q)}_{2nr} = \pi^{(q)}_{2nr}(\mathcal{H}W_{2nr}) v^{(q)}_{2nr} \) becomes a module for \( \mathcal{U}_q(u(n, n)) \) through the homomorphism \( \psi^{(r)}_q \) (5.30) and by adding the element \( \Xi^{(r)}_q \) (5.42). We need to investigate it as a \( \mathcal{U}_q^+(su(n, n)) \) module. We will not distinguish between the elements (5.36-5.39) and their actions in this module.

We aim to prove an analogue of Theorem 4.35. One interesting aspect is that while we will be working with the unital abelian algebra \( (\mathcal{H}W_{2nr})_{2nr}^Z \) generated by the elements \( (\mathbb{B}_x(y))^\dagger \), we, non-the-less, arrive in a natural way at quantum minors. We will, with obvious modifications, use the same notation as in §4. Now, as usual, a highest weight \( \Lambda \) and a highest weight vector \( v_\Lambda \) of a representation of \( \mathcal{U}_q(g) \) satisfies

\[
K^\xi v_\Lambda = q^{(\Lambda, \xi)} v_\Lambda
\]

(6.1)

for any \( \xi \) in the root lattice. We will further often assume that

\[
\Xi^{(r)}_q v_\Lambda = \zeta \cdot v_\Lambda
\]

(6.2)

in which case we replace \((\Lambda, v_\Lambda)\) by \(((\Lambda, \zeta), v(\Lambda, \zeta))\).

In the spirit of (6.1), roots and weights will be identified with their “classical” counterparts \((q = 1)\). Highest weight representations are defined analogously and, due to M. Rosso (38) and G. Lusztig (29), in the generic case, the dimensions of finite-dimensional highest weight modules are independent of \( q \).
Proceeding as in §4, \( \tilde{M}_q(V_{\Lambda}) \) now denotes the highest weight module of \( \mathcal{U}_q(su(n, n)) \) defined by the same highest weight data as \( M(V_{\Lambda}) \) and it is a quotient by the analogous invariant sub spaces.

What is not so clear, and must be established, is that there is a representation of \( \mathcal{U}_q(gl(r)) \) on \( \mathcal{F}^{(q)}_{2nr} \) which commutes with the action of \( \mathcal{U}_q(su(n, n)) \) as well as with \( \Xi^{(r)}_q \). Furthermore, it is not clear what should replace the highest weight vectors \( \Delta \) though the correct answer, namely \( \Delta_q \), seems so obvious. After all, the vector space \( \mathcal{F}^{(q)}_{2nr} \) has a basis built up from monomials in commuting operators acting on the “vacuum” - just like in the case of \( \mathcal{F}_{2nr} \), and hence, these two spaces are linearly isomorphic. As we shall see, this observation is not important; it is the actions that dictate what the highest weight vectors should be. Naturally they will be given in terms of the operators \( B^\dagger_i(k) \).

It follows immediately that \( \mathcal{F}^{(q)}_{2nr} = \pi^{(q)}_{2nr}(\mathcal{H}W_{2nr})\tilde{v}^{(q)}_{2nr} \) becomes a module for \( \mathcal{U}_q(u(n) \times u(n)) \) through the homomorphism \( \psi^{(r)}_q \) and the element \( \Xi^{(r)}_q \). The vectors in \( \mathcal{F}^{(q)}_{2nr} \) transform under symmetrized tensor products of the defining representation, so it is clear that we have the following analogue of Proposition 4.10 (c.f. Corollary 4.36):

**Proposition 6.1.** If \( r < n \), the most general \( \mathcal{U}_q(\mathfrak{g}^C) \)-type in \( \mathcal{F}_{2nr} \) has a q-highest weight of the form
\[
(a_1, \cdots, a_r, 0, \cdots), (b_1, \cdots, b_r, 0, \cdots), -a_1 - b_1 - r).
\]

If \( r \geq n \), the most general \( \mathcal{U}_q(\mathfrak{g}^C) \)-type in \( \mathcal{F}^{(q)}_{2nr} \) has a q-highest weight of the form
\[
(a_1, \cdots, a_{n-1}, 0), (b_1, \cdots, b_{n-1}, 0), -a_1 - b_1 - \bar{r}), \text{ with } a_{n-1}, b_{n-1} \geq 0,
\]
and \( \bar{r} = r, r + 1, r + 2, \ldots \).

The multiplicities are the same as in the classical case.

With these provisos, we can now formulate the main results of this case. The explanations and proofs will take up this last section of the article.

**Theorem 6.2.**
\[
\mathcal{F}^{(q)}_{2nr} = \bigoplus_{\xi \in \Sigma^{(r)}} \text{dim}(\xi) \tilde{M}_q(V_{\Lambda, \xi}^\mathfrak{C} \xi).
\]

When \( q \)-is real and positive, the representations \( M_q(V_{\Lambda}) \) are unitary.

The analogue of Proposition 4.36 is (compare also to Definition 4.2 and Proposition 4.3).

**Proposition 6.3.** If \( a = (a_1, \cdots, a_s) \), set \( \ell(a) = s \). Let
\[
\forall k \leq \min\{n, r\} : \Delta^q_k(x) = \sum_{\sigma \in S_k} (-q)^{sgn(\sigma)} \prod_{i=1}^k B_i^\dagger(\sigma(i)),
\]
\[
\forall \ell \leq \min\{n, r\} : \Delta^q_\ell(y) = \sum_{\sigma \in S_\ell} (-q)^{sgn(\sigma)} \prod_{i=1}^{\ell} B_i^\dagger_n(r - \sigma(i)).
\]
Further, let

\[ \Delta^q(x)^a = \prod_{k=1}^{\ell(a)} (\Delta^q_k(x))^{a_k}, \quad (6.8) \]

\[ \tilde{\Delta}^q(y)^b = \prod_{k=1}^{\ell(b)} \tilde{\Delta}^q_k(y)^{b_k}. \quad (6.9) \]

If \( \ell(a) + \ell(b) \leq r \), the vectors

\[ \Delta^q(x)^a \tilde{\Delta}^q(y)^b v_{2nr}^{(q)} \]

are highest weight vectors both for \( \mathcal{U}_q(\mathfrak{su}(n,n)) \) and \( \mathcal{U}_q(\mathfrak{gl}(r)) \). Furthermore, any joint highest weight vector is of this form.

6.1. The details; NYM. We wish to describe in detail the modules involved and not just appeal to the “well-known” fact that the representation theory at \( q \)-generic is the same as for \( q = 1 \). Recall the important result of de Consini, Eisenbud, and Procesi ([5]) in the classical case. Our main tool now is the article by M. Noumi, H. Yamada, and K. Mimachi (henceforth NYM; [34]), which will give us the analogue for the quantum case. Their work relies on the following result by M. Rosso (quoting [34])

**Theorem 6.4 ([38]).** If \( q \) is not a root of unity, any finite dimensional \( \mathcal{U}_q(\mathfrak{sl}(n,\mathbb{C})) \) module is completely reducible.

All our modules will be weight modules by construction.

In analogy with the classical case we set:

**Definition 6.5.** A top \( q \)-pluri-harmonic polynomial of weight \( (\Lambda, \zeta) \) (and of order \( r \)) is an element \( p \in \mathcal{F}_{2nr}^{(q)} \) which is annihilated by \( \mathcal{U}_q^{>0} \) and which satisfies

\[ \forall \alpha \in \Pi : K_{\alpha}p = q^{(\alpha, \Lambda)}p \text{ for some weight } \Lambda \quad (6.11) \]

\[ \Xi^{(r)}_q p = q^\zeta p. \quad (6.12) \]

Parallel to the classical case we now wish to introduce an extra module structure on \( \mathcal{F}_{2nr}^{(q)} \).

At first we will study two sub-spaces of \( \mathcal{F}_{2nr}^{(q)} \), namely one built up solely by applying operators \( B_i^\dagger(j) \) with \( i \leq n \), and one solely by \( B_{n+i}^\dagger(j) \) with \( i \leq n \), respectively, to the vacuum vector \( v_{2nr} \).

This is where ([34]) can be utilized. In it a bi-module structure on a certain algebra, to be defined right below, is introduced. We will set up a vector space isomorphism between this algebra and each of the two mentioned sub-spaces of \( \mathcal{F}_{2nr}^{(q)} \), thus furnishing these subspaces with bi-module structures too.

Here are the notations and structures from ([34]):
The coordinate ring $\mathcal{A}(r, s, \mathbb{C})$ is the $\mathbb{C}$ algebra generated by variables $w_{i,j}$ with $1 \leq i \leq r$ and $1 \leq j \leq s$ satisfying the relations

$$w_{ij}w_{ik} = qw_{ik}w_{ij} (j < k), \quad (6.13)$$
$$w_{i\ell}w_{jk} = w_{jk}w_{i\ell} (i < j, k < \ell), \quad (6.14)$$
$$w_{ik}w_{j\ell} - w_{j\ell}w_{ik} = (q - q^{-1})w_{i\ell}w_{jk} (i < j, k < \ell). \quad (6.15)$$

In $su(N)$ we identify $\mu_i \leftrightarrow \varepsilon_i - \varepsilon_{i+1}$ for any simple root $\mu_i, i = 1, \ldots, N - 1$. Here, $\{\varepsilon_1, \ldots, \varepsilon_N\}$ is the standard orthonormal basis of $\mathbb{R}^N$. $U_q(su(N))$ is then given in its usual guise, compatible with this.

Slightly adapted and expanded to our notation we now cite:

**Theorem 6.6.** [34, (1.35.1)-(1.35.c)] There is a left action by $U_q(u(s))$ and a right action by $U_q(u(r))$ on the vector space spanned by the elements $w_{i,j}; i = 1, \ldots, s; j = 1, \ldots, r$ given as follows;

$$L_k \star w_{ij} = q^{\langle \varepsilon_k, \varepsilon_j \rangle} w_{ij}, \quad (6.16)$$
$$K_{\mu} \star w_{ij} = q^{\langle \mu_k, \varepsilon_j \rangle} w_{ij} \quad (6.17)$$
$$= L_k \star L_{k+1}^{-1} \star w_{ij}, \quad (6.18)$$
$$E_{\mu_k} \star w_{ij} = \delta_{j,k+1} w_{i,j-1}, \quad (6.19)$$
$$F_{\mu_k} \star w_{ij} = \delta_{j,k} w_{i,j+1}, \quad (6.20)$$
$$w_{ij} \star L_k = q^{\langle \varepsilon_k, \varepsilon_i \rangle} w_{ij}, \quad (6.21)$$
$$w_{ij} \star K_{\mu} = q^{\langle \mu_k, \varepsilon_i \rangle} w_{ij} \quad (6.22)$$
$$= w_{ij} \star L_k \star L_{k+1}^{-1}, \quad (6.23)$$
$$w_{ij} \star E_{\mu_k} = \delta_{i,k+1} w_{i+1,j}, \quad (6.24)$$
$$w_{ij} \star F_{\mu_k} = \delta_{i,k} w_{i-1,j}. \quad (6.25)$$

The stated actions on the elements $w_{ij}$ do indeed commute, and from this one gets the actions from the left and right on $\mathcal{A}(s, r, \mathbb{C})$: If $\triangle a = \sum_i a_i^1 \otimes a_i^2$ then

$$a \star (\phi \psi) = \sum_i (a_i^1 \star \phi)(a_i^2 \star \psi), \quad (6.26)$$
$$(\phi \psi) \star a = \sum_i (\phi \star a_i^1)(\psi \star a_i^2). \quad (6.27)$$

For reference, we will call this the left NYM action, and the right NYM action, respectively. The resulting algebras of operators will be denoted the right NYM operators and the left NYM operators. In the following, whenever the symbol $\star$ appears, it refers to one of these actions. It will be clear from its position if it is a right or a left action.

There is in [34] even an action on a localization by the quantum determinant of this algebra, but we shall not need this level of sophistication.
We will give explicitly the actions below. The co-product used in (34) is different from ours. It is the one introduced by Drinfeld and Jimbo ([7], [24]). Given in its simplest $U_q(sl(2, \mathbb{C}))$ version for generators $E, F, K^\pm$ it is

$$\Delta_{DJ}E = E \otimes K^{-1/2} + K^{1/2} \otimes E, \quad (6.28)$$

$$\Delta_{DJ}F = F \otimes K^{-1/2} + K^{1/2} \otimes F, \quad (6.29)$$

$$\Delta_{DJ}K^\pm = K^\pm \otimes K^\pm. \quad (6.30)$$

**Remark 6.7.** The above necessitates the introduction of a fixed choice of $q^{1/2}$. After that one can introduce operators $K^{\pm \frac{1}{2}}$. Using this, we will show that one can adapt their results to ours. The factors $K^{\pm \frac{1}{2}}$ and $q^{\pm \frac{1}{2}}$ are inherent to NYM, and hence cannot be avoided when we use their results. Once we know that our results are true, we could then reformulate them without these factors, but we will refrain from doing this cumbersome exercise, as it adds little insight.

In NYM = [34] [p. 36] the notion of a $q$-minor $\triangle_q$ is introduced. It is the one given in (2.20) with $a = q$.

We will state an analogue to (6.8): Set, for $m = (m_1, \ldots, m_r) \in \mathbb{N}_0^r$,

$$\triangle_q(w)^m = \prod_{i=1}^r \triangle_{q,i}(w)^{m_i}. \quad (6.31)$$

The following is proved in (34) (Combine Theorem 2.12 and Theorem 2.4 ibid. Also see the argument at the end of Section 2.3 ibid.)

**Theorem 6.8.** [34] As a bi-module,

$$\mathcal{A}(n, n, \mathbb{C}) = \bigoplus_{m \in \mathbb{N}_0^r} W(m), \quad (6.32)$$

where $W(m)$ is the irreducible bi-module with highest weight vector $\triangle_q(w)^m$.

**Remark 6.9.** We stress that the minors considered in Section 5 use $a = q^{-1}$. They are computed in algebras generated by the variables $\mathbb{W}_{i,j}^{(r)}$ whose terms contain at least one $\mathbb{B}_{i,j}^{(k)}(r)$ and one $\mathbb{B}_{n+j}^{(k)}(r)$. See (5.68) for a more precise statement. The variables $w_{ij}$ we now consider are hence not at all like the variables $\mathbb{W}_{i,j}^{(r)}$.

There is a further point that should be noted: In the bi-module structure (to be defined presently) the right action has an interchange of $E \rightarrow F$ so that a highest weight vector from the right action is annihilated by elements $F_a$.

After this, Theorem 6.8 is seen as being a $q$-analogue of the Peter-Weyl Theorem. As we shall see later in Proposition 6.13 this is precisely what we shall need.
6.2. The left and right NYM actions. We here make a general definition of some quantum multiplication, quantum differentiation, and quantum scale operators in an algebra $\mathcal{A}$ (or even just a vector space) in which there is a (PBW) basis defined in terms of some $N$ “variables” $x_i$ which are already ordered so that $i < j \iff x_i < x_j$ and $x_1$ is placed furthest to the left.

$$\mathcal{B} = \{ x^b = x_1^{b_1} \cdots x_N^{b_N} \in \mathcal{A} \mid b \in \mathbb{N}_0^N \}. \quad (6.33)$$

**Definition 6.10.** $\forall i = 1, \ldots, N$:

$$M_i x^b = x^{b'} \text{ where } b' = b + e_i, \quad (6.34)$$

$$D_i x^b = [b_i] q x^{b''} \text{ where } b'' = b - e, \quad (6.35)$$

$$H_i^{\pm 1} x^b = q^{\pm b_i} x^b. \quad (6.36)$$

The operators $M_i, D_i,$ and $H_i^{\pm}$ of course depend on the basis. Below we shall encounter bases for some special choices of $\sigma \in S_N$, $B_\sigma = \{ x^b = x_{\sigma(1)}^{b_1} \cdots x_{\sigma(N)}^{b_N} \mid b \in \mathbb{N}_0^N \}, \quad (6.37)$

resulting from different orderings of the variables. In at least one instance it will hold, for some $\sigma_0 \in S_N$ that

$$\forall b \in \mathbb{N}_0^N : x_{\sigma_0(1)}^{b_0(1)} \cdots x_{\sigma_0(N)}^{b_0(N)} = x_1^{b_1} \cdots x_N^{b_N}. \quad (6.38)$$

In this case we say that the bases are equivalent. Clearly, in such a case the resulting operators $M, D,$ and $H^\pm$ will be the same.

We can use any such basis $\mathcal{B}$ to set up a vector space isomorphism $\mathcal{T}_{\mathcal{A}, \mathcal{P}_N}^R$ between $\mathcal{A}$ and the space $\mathcal{P}^N = \mathcal{P}(z_1, \cdots, z_n)$ of complex polynomials in $N$ variables

$$\mathcal{T}_{\mathcal{A}, \mathcal{P}_N}^R : x_1^{b_1} \cdots x_N^{b_N} = x^b \rightarrow z^b = z_1^{b_1} \cdots z_N^{b_N}. \quad (6.39)$$

In this way, any operator on $\mathcal{A}$ that can be expressed in terms of the operators $M, D,$ and $H^\pm$ can be transported to $\mathcal{P}^N$, and vice versa.

Any two PBW bases of $\mathcal{P}^N$ of the above kind yield the same operators $M, D, H^\pm$.

We consider an order $>_R$ of the pairs $(i, j)$ as follows:

$$(i, j) >_R (s, t) \iff \begin{cases} j < t \text{ or} \\ j = t, s < i. \end{cases} \quad (6.40)$$

We write a variable $w_{ij}$ to the left of a variable $w_{st}$ if $(i, j) >_R (s, t)$. This way we get a PBW basis $\mathcal{B}_R$ consisting of monomials in the variables $w_{ij}$. Using $(6.22, 6.25)$ repeatedly we get

$$\left( \sum_\beta \left( \prod_{(i,j)>_R(a,\beta)} w_{ij}^{b_{ij}} \right) w_{a,\beta}^{b_{a,\beta}} \left( \prod_{(a,\beta)>_R(s,t)} w_{st}^{b_{st}} \right) \right) \ast E_a = \quad (6.41)$$

$$\sum_\beta \left( \prod_{(i,j)>_R(a,\beta)} w_{ij}^{b_{ij}} \right) \ast K_a^{1/2} \left( w_{a,\beta}^{b_{a,\beta}} \ast E_a \right) \left( \prod_{(a,\beta)>_R(s,t)} w_{st}^{b_{st}} \right) \ast K_a^{-1/2}. \quad (6.42)$$

57
Here, the expressions in the brackets can easily be computed. This, together with an issue of a change \( q \leftrightarrow q^{-1} \) between NYM and our setup, is actually the reason for choosing this particular basis.

The right action of \( F_a \) can be computed analogously. We denote by \( E^R_a(\mathcal{B}^R) \) and \( F^R_a(\mathcal{B}^R) \), respectively, the right NYM operators on \( \mathcal{P}_{s,r} \) computed in the basis \( \mathcal{B}^R \). Finally the right actions \( L^R_a(\mathcal{B}^r) \), \( K^R_a(\mathcal{B}^r) \) of \( K_a \) are similarly determined. To state the result, we define the symbols \( H_{\pm}^{a,b_1}, H_{\pm}^{a_1,b} \), etc. in analogy with the symbols \( L_{a,b_1}^\pm, L_{a_1,b}^\pm \), etc. of §5. We can then state the result:

**Proposition 6.11** (Right NYM operators).

\[
E^R_a(\mathcal{B}^r) = q^{1/2} \sum_{\ell=1}^s D_{a,\ell} M_{a+1,\ell} H_{a,\ell+1}^{-1/2} H_{a+1,\ell+1}^{-1/2} H_{a,\ell+1}^{1/2} H_{a+1,\ell+1}^{1/2} (K^r_a)^{-1} \quad (6.43)
\]

\[
= q^{1/2} \sum_{\ell=1}^s D_{a,\ell} M_{a+1,\ell} H_{a,\ell+1}^{-1} H_{a+1,\ell+1}^{-1} (K^r_a)^{-1/2}. \quad (6.44)
\]

Similarly,

\[
F^R_a(\mathcal{B}^r) = q^{1/2} \sum_{\ell=1}^s D_{a+1,\ell} M_{a,\ell} H_{a,\ell}^{-1/2} H_{a+1,\ell}^{1/2} H_{a,\ell}^{1/2} H_{a+1,\ell}^{-1/2} H_{a,\ell+1}^{-1} (K^r_a), \quad (6.45)
\]

\[
L^R_a(\mathcal{B}^r) = \prod_j H_{a,j}, \quad (6.46)
\]

\[
K^R_{\mu_k}(\mathcal{B}^r) = \prod_j H_{k,j} H_{k+1,j}^{-1}. \quad (6.47)
\]

We now introduce a linear isometry \( \mathcal{T}^B_{s,r} : \mathcal{P}_{s,r} \rightarrow \mathcal{F}^{(q)}_{sr} \) given on a basis \( z^b = \prod_{k,\ell} (z_{k,\ell})^{b_{k,\ell}} \) by

\[
\mathcal{T}^B_{s,r}(z^b) = \prod_{k,\ell} (B^\dagger_k(\ell))^{b_{k,\ell}} \cdot v^{(q)}_{sr}. \quad (6.48)
\]

The operators \( D_{i,j}, H_{i,j}^{\pm} \), and \( M_{i,j} \) are transported to \( \mathcal{F}^{(q)}_{sr} \) by setting

\[
D_{i,j} v^{(q)}_{sr} = 0, \quad H_{i,j}^{\pm} v^{(q)}_{sr} = v^{(q)}_{sr}, \quad \text{and} \quad M_{i,j} v^{(q)}_{sr} = B^\dagger_i(j) v^{(q)}_{sr}. \quad (6.49)
\]

Using the linear isomorphism \( \mathcal{T}^B_{A,P_N} \) with \( \mathcal{A} = \mathcal{A}(s, r, \mathbb{C}) \) and \( N = sr \), as well as the linear isomorphism \( \mathcal{T}^B_{s,r} \), it follows that \( \mathcal{F}^{(q)}_{sr} \) as well as \( \mathcal{P}_{s,r} \) become bi-modules.

In correspondence with (5.28) we have

\[
\mathcal{F}_{2nr}^{(q)} = \mathcal{F}_{nr}^{X,(q)} \otimes \mathcal{F}_{nr}^{Y,(q)}, \quad (6.50)
\]

and we have

\[
\mathcal{P}_{2nr} = \mathcal{P}_{nr}^X \otimes \mathcal{P}_{nr}^Y, \quad (6.51)
\]

\[
\mathcal{A}(r, 2n, \mathbb{C}) = \mathcal{A}^X(r, n, \mathbb{C}) \otimes \mathcal{A}^Y(r, n, \mathbb{C}). \quad (6.52)
\]
Here, \( \mathcal{P}_{nr}^X \) has variables \( z_{ij} \) with \( 1 \leq i \leq n \) and \( 1 \leq j \leq r \) while \( \mathcal{P}_{nr}^Y \) has variables \( z_{ij} \) with \( n+1 \leq i \leq 2n \) and \( 1 \leq j \leq r \). The spaces \( \mathcal{A}_X^X(r, n, \mathbb{C}) \) and \( \mathcal{A}_X^Y(r, n, \mathbb{C}) \) are defined analogously.

In the same spirit,

\[
\mathcal{F}_{nr}^X(q) = \mathcal{H} \mathcal{W}_{nr}^X \cdot v_{2nr}^{(q)}, \quad (6.53)
\]

\[
\mathcal{F}_{nr}^Y(q) = \mathcal{H} \mathcal{W}_{nr}^Y \cdot v_{2nr}^{(q)}. \quad (6.54)
\]

Under linear isomorphisms, the spaces labeled by an \( X \) are equivalent, as are the spaces labeled by \( Y \). A (say, left) operator \( G \) on a space labeled by, say, \( X \) may occasionally get a label \( G(X) \), and similarly for \( Y \).

In conclusion, we now have a bi-module structure on the \( q \)-Fock module \( \mathcal{F}_{sr}^{(q)} \), or, equivalently, on \( \mathcal{P}_{sr} \).

It will become important later that we do not just use the bi-module structure on \( \mathcal{F}_{2nr}^{(q)} \) but use bi-module structures on \( \mathcal{F}_{nr}^X(q) \) and \( \mathcal{F}_{nr}^Y(q) \) where the left action on the latter is not the NYM action, but a modified version thereof.

Returning to the formulas \( (5.36-5.39) \), it is clear that they also can be formulated in \( \mathcal{F}_{2nr}^{(q)} \), or, equivalently, on \( \mathcal{P}_{2nr} \). The operators \( x^{(r)}_j, x = e, f \) can even be viewed as operators on \( \mathcal{P}_{nr}^X \) when \( 1 \leq j \leq n \) and on \( \mathcal{P}_{nr}^Y \) when \( n+1 \leq j \leq 2n \).

We list these formulas for comparison (Notice: We compute this in the basis \( \mathcal{B}^R \).):

**Proposition 6.12.**

\[
e^{(r)}_\beta = \sum_{i=1}^{r} q^{-i+1} D_{1,i} D_{n+1,i} H_{1,(i-1)}^{-1} H_{n+1,(i-1)}^{-1} \quad (6.55)
\]

\[
f^{(r)}_\beta = \sum_{i=1}^{r} q^{-i} M_{1,i} M_{n+1,i} H_{1,(i+1)} H_{n+1,(i+1)} \quad (6.56)
\]

\[
e^{(r)}_j = \sum_{i=1}^{r} D_{j+1,i} M_{j,i} H_{j,(i-1)} H_{j,(i-1)} \quad (6.57)
\]

\[
f^{(r)}_j = \sum_{i=1}^{r} D_{j,i} M_{j+1,i} H_{j,(i+1)} H_{j,(i+1)} \quad (6.58)
\]

To compare with our expressions we use generally \( E = q^{-1/2} e K^{1/2} \) and \( F = q^{-1/2} f K^{-1/2} \) but with \( e, f \) computed from the NYM expressions. These are also NYM operators.

Comparing these formulas to those in \( (6.57, 6.58) \) we get (notice that \( E \leftrightarrow f \) and \( F \leftrightarrow e \)): 
Proposition 6.13.

\[ E^R_a(B^r) = q^{1/2} f_a^{(r)} (K^r_a)^{-1/2}, \]
\[ F^R_a(B^r) = q^{1/2} e_a^{(r)} (K^r_a)^{1/2}. \]  \hfill (6.59) \hfill (6.60)

Corollary 6.14. The operators \( e_a^{(r)}, f_a^{(r)} \) are right NYM operators. In particular, they commute with all operators acting from the left.

Proof: (of Corollary 6.14). This follows immediately since the operators \((K^r_a)\) are right operators. \hfill □

We can compute the left NYM operators analogously, but here we chose an order \( >_L \) defined as follows:

\[ (i, j) >_L (s, t) \iff \left\{ \begin{array}{l} i < s \text{ or} \\ i = s, t < j. \end{array} \right. \]  \hfill (6.61)

Corresponding to this we get a PBW basis \( \mathcal{B}^L \). The computation of the left NYM operators \( E^L_a(B^L) \) and \( F^L_a(B^L) \) in this basis follows analogously. In fact, one can simply interchange lower indices while making the switch \( E \leftrightarrow F \). One gets:

Proposition 6.15 (Left NYM operators).

\[ E^L_a(B^L) = q^{-1/2} \sum_{\ell=1}^s D_{\ell,a+1} M_{\ell,a} H_{\ell-1,\ell,a+1}^{-1/2} H_{\ell-1,\ell,a}^{1/2} H_{\ell,\ell+1}^{1/2} H_{\ell+1,\ell+1}^{1/2}, \]
\[ F^L_a(B^L) = q^{-1/2} \sum_{\ell=1}^s D_{\ell,a+1} M_{\ell,a} H_{\ell,\ell+1}^{-1/2} H_{\ell-1,\ell,a}^{1/2} H_{\ell-1,\ell+1}^{1/2} H_{\ell+1,\ell+1}^{1/2}, \]
\[ L^L_a(B^r) = \prod_j H_{j,a}, \]
\[ K^L_{\mu_k}(B^r) = \prod_j H_{j,k} H_{j,k+1}^{-1}. \]  \hfill (6.62) \hfill (6.63) \hfill (6.64) \hfill (6.65)

Lemma 6.16. Set \( K_\beta = \prod_\ell H_{1,\ell} H_{n+1,\ell}. \) Then \( K_\beta \) commutes with all left NYM operators.

We now perform some computations with the aim of finding some left NYM operators that commute with \( e_\beta \) and \( f_\beta. \) Recalling the homomorphism \( \Gamma^{(r)}_3 \) of Proposition 3.27, our strategy will be to look for some left operators on \( \mathcal{A}^X(r,n,C) \) and \( \mathcal{A}^Y(r,n,C), \) respectively. Such operators will be labeled by \( X,Y, \) respectively. We restrict our search to a small class of promising operators:

Set
\[ A_a := H_{1,a+1}^{-\varepsilon_2} H_{n+1,a}^{\beta_2} H_{1,a+1}^{\varepsilon_1} H_{n+1,a}^{-\beta_1}, \]
\[ B_a := H_{1,a+1}^{-\varepsilon_4} H_{n+1,a}^{\beta_4} H_{1,a+1}^{\varepsilon_3} H_{n+1,a}^{-\beta_3}. \]  \hfill (6.66)

Then,
The operator \( A \) and the above computations we easily reach:

\[
\begin{align*}
D_{1,a+1}M_{1,a}A_a & - e_\beta D_{1,a+1}M_{1,a}A_a = \\
q^{-a+1} & (q^{-\varepsilon_1-\beta_1}M_{1,a}D_{1,a} - D_{1,a}M_{1,a}) D_{1,a+1}D_{n+1,a}A_aH_{1,a-1\downarrow}^{-1}H_{n+1,a-1\downarrow}^{-1} + \\
q^{-a} & (q^{\varepsilon_2+\beta_2} - 1) D_{1,a+1}D_{n+1,a+1}H_{1,a\downarrow}^{-1}H_{n+1,a\downarrow}^{-1} D_{1,a+1}M_{1,a}A_a,
\end{align*}
\]

\[
D_{n+1,a}M_{n+1,a+1}Ba e_\beta - e_\beta D_{n+1,a}M_{n+1,a+1}Ba =
q^{-a} (q^{\varepsilon_4+\beta_4}M_{n+1,a+1}D_{n+1,a+1} - qD_{n+1,a+1}M_{n+1,a+1}) D_{n+1,a}D_{n+1,a+1}H_{1,a\downarrow}^{-1}H_{n+1,a\downarrow}^{-1} + \\
q^{-a+1} (q^{-\varepsilon_3-\beta_3} - 1) D_{1,a}D_{n+1,a}H_{1,a\downarrow}^{-1}H_{n+1,a\downarrow}^{-1} D_{1,a}M_{n+1,a+1}B_a,
\]

\[
D_{1,a+1}M_{1,a}A_a f_\beta - f_\beta D_{1,a+1}M_{1,a}A_a = \]

\[
q^{-a-1} (q^{-\varepsilon_2-\beta_2}D_{1,a+1}M_{1,a+1} - M_{1,a+1}D_{1,a+1}) M_{1,a}M_{n+1,a+1}A_aH_{1,a+2\uparrow}H_{n+1,a+2\uparrow} + \\
q^{-a} (q^{\varepsilon_1+\beta_1} - 1) M_{1,a}M_{n+1,a+1}H_{1,a+1\uparrow}H_{n+1,a+1\uparrow} D_{1,a+1}M_{1,a}B_a,
\]

and

\[
D_{n+1,a}M_{n+1,a+1}B_a f_\beta - f_\beta D_{n+1,a}M_{n+1,a+1}B_a =
q^{-a} (q^{\varepsilon_3+\beta_3}D_{n+1,a}M_{n+1,a} - qM_{n+1,a}D_{n+1,a}) M_{1,a}M_{n+1,a+1}B_aH_{1,a+1\uparrow}H_{n+1,a+1\uparrow} + \\
q^{-a-1} (q^{-\varepsilon_4-\beta_4} - 1) M_{1,a+1}M_{n+1,a+1}H_{1,a+2\uparrow}H_{n+1,a+2\uparrow} D_{n+1,a}M_{n+1,a+1}B_a.
\]

The operators \( A_a, B_a \) of course depend upon the four variables \( \varepsilon_i, \beta_i; i = 1, 2, 3, 4 \).

From now on we express the relevant operators in terms of the basis \( B^L \).

Using the above computations we easily reach:

**Proposition 6.17.** The operator

\[
D_{1,a+1}M_{1,a}A_a - \alpha D_{n+1,a}M_{n+1,a+1}B_a
\]

commutes with \( e_\beta \) and \( f_\beta \) if and only if \( \alpha = 1, \varepsilon_1 + \beta_1 + 1 = 0, \varepsilon_2 + \beta_2 + 1 = 0, \varepsilon_3 + \beta_3 = 0, \varepsilon_4 + \beta_4 = 0, \varepsilon_1 = \varepsilon_3, \) and \( \varepsilon_2 = \varepsilon_4 \).

Because of this result we now set:

**Definition 6.18.**

\[
E_a(X) = \sum_{\ell=1}^{n} D_{\ell,a+1}M_{\ell,a}H_{\ell-1\downarrow,a}H_{\ell-1\downarrow,a+1}^{-1}H_{n+1,a}^{-1}H_{n+1,a+1}
\]

\[
= q^{1/2}E_a^L(X)(B^L)(K_a^L(X))^{1/2}(K_a^L(Y))^{-1}.
\]

Similarly,

\[
F_a(X) = \sum_{\ell=1}^{n} D_{\ell,a}M_{\ell,a+1}H_{\ell+1\uparrow,a}^{-1}H_{\ell+1\uparrow,a+1}
\]

\[
= q^{1/2}F_a^L(X)(B^L)(K_a^L(X))^{-1/2}.
\]
In the same way, we define elements \( E_a(Y), F_a(Y) \):

\[
E_a(Y) = q^{1/2} E_a^L(Y) (B^L)(K^L_a(Y))^{1/2} (K^L_a(X))^{-1}, \quad \text{and} \quad (6.77)
\]

\[
F_a(Y) = q^{1/2} F_a^L(Y) (B^L)(K^L_a(Y))^{-1/2}. \quad (6.78)
\]

**Corollary 6.19.** The elements \( (E_a(X) - F_a(Y)) \) and \( (E_a(Y) - F_a(X)) \) commute with \( e_\beta, f_\beta \).

**Proof:** The result follows follows from Proposition 6.17 as far as the first term is concerned since the term has been constructed so that the full commutativity when \( \ell \neq 1 \) is covered. The second equation follows by symmetry. \( \square \)

**Proposition 6.20.**

\[
E_a^L(Y) (B^L)(K^L_a(X))^{1/2} (K^L_a(Y))^{-1} - F_a^L(Y) (B^L)(K^L_a(Y))^{-1/2}
\]

and

\[
F_a^L(Y) (B^L)(K^L_a(Y))^{1/2} (K^L_a(X))^{-1} - F_a^L(X) (B^L)(K^L_a(X))^{-1/2}
\]

commute with \( e_\beta, f_\beta \).

**Proof:** The two expressions are \( q^{-1/2}(E_a(X) - F_a(Y)) \) and \( q^{-1/2}(E_a(Y) - F_a(X)) \), respectively. \( \square \)

Let us write \( k_a(Z) = K^L_a(Z) \), \( e_a(Z) = E^L_a(Z)(B^L) \), and \( f_a(Z) = F^L_a(Z)(B^L) \); \( Z = X, Y \). Notice that the operators \( e_a(Z), f_a(Z), k_a(Z) \) satisfy the \( q \)-Serre relations. In particular, \( [e_a(Z), f_a(Z)] = \frac{k_a(Z) - k_a(Z)^{-1}}{q - q^{-1}} ; Z = X, Y \).

Notice that

\[
(k_a(Y)k_a(Y)^{-1}) = L_a(X) L_a^{-1}(Y) L_{a+1}^{-1}(X) L_{a+1}(Y), \quad (6.81)
\]

and any power of \( L_a(X) L_a^{-1}(Y) \) commutes with \( e_\beta, f_\beta \).

From this we conclude:

**Proposition 6.21.** The following left NYM operators

\[
e_a = e_a(X)k_a(Y)^{-1/2} - f_a(Y)k_a(X)^{-1/2}, \quad \text{and} \quad (6.82)
\]

\[
f_a = f_a(X)k_a(Y)^{-1/2} - e_a(Y)k_a(X)^{-1/2} \quad (6.83)
\]

commute, for any \( a = 1, \cdots, r \), with \( e_\beta, f_\beta \) as well as with the operators \( e_j^{(r)}, f_j^{(r)} \) for any \( j \in \{ 1, \ldots, n - 1, n + 1, \ldots, 2n - 1 \} \).

A simple computation gives:

**Proposition 6.22.**

\[
[e_a, f_a] = \frac{k_a(X)k_a(Y)^{-1} - k_a(Y)k_a(X)^{-1}}{q - q^{-1}}. \quad (6.84)
\]

Set \( k_a = k_a(X)k_a(Y)^{-1} \).
Proposition 6.23 (Drinfeld Double). The elements $e_a, f_a, k_a^\pm 1$, $a = 1, \ldots, r$ satisfy the quantum Serre relations for $su_q(r)$.

Proof: First of all, it is easy to see that $[e_a, f_b] = 0$ if $a \neq b$. The relations involving $k_a^\pm 1$ are also straightforward. To address the equations for the quantum adjoint, consider two different elements $e_a, e_b$. Write, in straightforward notation, $e_a = \alpha - \beta$, and $e_b = \gamma - \delta$. We must then prove that
\[(\alpha - \beta)(\alpha - \beta)(\gamma - \delta) - [2]_q(\alpha - \beta)(\gamma - \delta)(\alpha - \beta) + (\gamma - \delta)(\alpha - \beta)(\alpha - \beta) = 0. \quad (6.85)\]
Observing that $\alpha \delta = q^{-1} \delta \alpha$, $\beta \gamma = q \gamma \beta$, $\alpha \beta = q^2 \beta \alpha$, and $\gamma \delta = q^2 \delta \gamma$, the equations involving “cross-terms” are seen to vanish. Since the elements $e_a(Z), f_a(Z)$ already satisfy the $q$-Serre, the claim follows.

See e.g. J. Xiao ([50]) for a study of the Drinfeld Double.

Definition 6.24. We denote by $U_q^D(u(r))$ the particular presentation of $U_q(u(r))$ thus constructed.

Proposition 6.25. There is a representation of $U_q^D(u(r))$ on $F_{2nr}^{(q)}$.

Proof: We can use the generators $k_a^\pm 1, e_a,$ and $f_a$ defined above. \qed

We then obtain:

Theorem 6.26. The representations of $U_q(u(n, n))$ and $U_q^D(u(r))$ on $F_{2nr}^{(q)}$ commute.

There is also an analogue of Proposition 3.28.

Proposition 6.27. An element $h \in \mathcal{HW}_{2nr}$ commutes with $\psi_q^{(r)}(U_q(u(n, n)^C))$ if and only $h \in U_q^D(u(r)^C)$.

Proof: (Sketched) We have that $h$ is a polynomial in operators $D_*, M_*$, and $K_*^\pm 1$. Focusing on, say $\mathcal{HW}_{nr}^X$, we have that $h$ commutes with $\psi_q^{(r)}(U_q(u(n))_X^C)$. Via the linear isomorphisms, we can view these as acting on $A^X(r, n, C)$. Since irreducible representations of $\psi_q^{(r)}(U_q(u(n))_X^C)$ of a specific type in $A^X(r, n, C)$ all occur in the same degree, it follows that $h$ must preserve these degrees. We can then, crucially, employ the $q$-commutator result of R. B. Zhang ([51]). It is clear that we have all of $U_q(gl(n)^C)_X$ acting from the right. Thus, this piece of $h$ must be a left NYM operator.

By similar reasoning involving $A^Y(r, n, C)$ we eventually conclude, similarly to the classical case, that
\[h \in (U_q(u(r))_X^C)(U_q(u(r))_Y^C). \quad (6.86)\]
There is now the proviso that we need operators $k_a(X)^{\pm 1/2}$ and $k_a(Y)^{\pm 1/2}$ acting as scaling operators in the representations. This involves a simple choosing of a $q^{1/2}$.

Parallel to the classical case, the center of $\mathcal{HW}_{2nr}$ is $C$ as follows by considering commutators of the elements $K_*^\pm 1$. We here use that $q$ is not a root of unity. From then on, the proof proceeds in the same way. \qed
Proof of Theorem 6.2 and Proposition 6.3: It follows from Theorem 6.8 that, as a $\mathcal{U}_q(u(n)) \times \mathcal{U}_q(u(n)) \times \mathcal{U}_q(u(r)) \times \mathcal{U}_q(u(r))$ module, the highest weight vectors in $\mathcal{F}^{(q)}_{2nr}$ are given as
\[ \forall \mathbf{m}_1, \mathbf{n}_1 \in \mathbb{N}_0^r : \quad \Delta_q^{m_1}(x) \Delta_q^{n_1}(y) \cdot v^{(q)}_{2nr}. \] (6.87)

We can then see, by direct evaluation of $e_\beta$ on these, that the element $\Delta_q^{m}(x) \Delta_q^{n}(y)$ is a top $q$-pluri-harmonic polynomial if $(\ell(m), \ell(n))$ (6.88)

In this case, this vector is the highest weight vector for an irreducible $\mathcal{U}_q(u(r))$ module of highest weight $(m_1, \ldots, m_{\ell(m)}, 0, \ldots, 0, -n_{\ell(n)}, \ldots, -n_1)$. The non-zero vectors in this module are all top $q$-pluri-harmonic polynomials of highest weight
\[ (\Lambda, \zeta) = (m, n, -r - m_1 - n_1, |m| - |n|). \] (6.89)

By weight comparisons (c.f. (38)), there can be no more top $q$-pluri-harmonic polynomials than the ones listed.

After this, it is clear that we have the same correspondence between a special class of irreducible representations of $\mathcal{U}_q(u(r))$, though with a new $q$-weight interpretation of $(\Lambda, \zeta)\xi$, as in Definition 4.32.

With this, we also have a Proof of Theorem 6.2. □

Remark 6.28. There remains now perhaps only to discuss what “quantized covariant differential operators” should be. In line with Remark 4.14 everything in the beginning carries nicely over, indeed all the way to (4.86). After that one can take the path of using operators $D_*, M_*$, and $K^\pm_*$ defined in specific bases. This line will be pursued elsewhere.
