Inclusions of $C^*$-algebras arising from fixed-point algebras

Siegfried Echterhoff and Mikael Rørdam

Abstract. We examine inclusions of $C^*$-algebras of the form $A^H \subseteq A \rtimes_r G$, where $G$ and $H$ are groups acting on a unital simple $C^*$-algebra $A$ by outer automorphisms and $H$ is finite. It follows from a theorem of Izumi that $A^H \subseteq A$ is $C^*$-irreducible, in the sense that all intermediate $C^*$-algebras are simple. We show that $A^H \subseteq A \rtimes_r G$ is $C^*$-irreducible for all $G$ and $H$ as above if and only if $G$ and $H$ have trivial intersection in the outer automorphisms of $A$, and we give a Galois type classification of all intermediate $C^*$-algebras in the case when $H$ is abelian and the two actions of $G$ and $H$ on $A$ commute. We illustrate these results with examples of outer group actions on the irrational rotation $C^*$-algebras. We exhibit, among other examples, $C^*$-irreducible inclusions of AF-algebras that have intermediate $C^*$-algebras that are not AF-algebras; in fact, the irrational rotation $C^*$-algebra appears as an intermediate $C^*$-algebra.

1. Introduction

Inclusions of unital simple $C^*$-algebras with the property that all intermediate $C^*$-algebras are simple were characterized and labeled $C^*$-irreducible in the recent paper [13] by the second named author. A well-known and classic result of Kishimoto [11] states that whenever a group $G$ acts by outer automorphisms on a simple $C^*$-algebra $A$, then the reduced crossed product $A \rtimes_r G$ is simple as well. It follows easily from the proof of this theorem that the inclusion $A \subseteq A \rtimes_r G$ is $C^*$-irreducible, when $A$ in addition is unital, cf. [13, Theorem 5.8]. Moreover, Izumi [10, Corollary 6.6] in the case of finite $G$, and Cameron and Smith [4, Theorem 3.5] in the general case established a Galois correspondence between intermediate $C^*$-algebras $A \subseteq D \subseteq A \rtimes_r G$ and subgroups $L$ of $G$, via $L \mapsto D = A \rtimes_r L$.

It was observed by Rosenberg [14] that if $H$ is any finite group acting (outer or not) on any $C^*$-algebra $A$, then $A^H$ is isomorphic to a hereditary sub-$C^*$-algebra of $A \rtimes H$. In particular, if $A$ is simple and the action of $H$ on $A$ is by outer automorphisms, then $A^H$ is simple. A result of Izumi [10, Corollary 6.6] shows that the inclusion $A^H \subseteq A$ then is $C^*$-irreducible and that all intermediate algebras are of the form $A^H \subseteq A^L \subseteq A$ for subgroups $L$ of $H$. This mirrors the situation of crossed products by finite groups, and Izumi

Keywords. Irreducible inclusion of $C^*$-algebras, crossed product, fixed-point algebra, irrational rotation algebra.
indeed directly relates the fixed-point algebra inclusion to the corresponding crossed-product inclusion via a version of Jones basic construction (see [10, Corollary 3.12]).

Bisch and Haagerup considered in their paper [2] subfactors of the form \( P^H \subseteq P \rtimes G \) arising from outer actions of two finite groups \( H \) and \( G \) on a \( \text{II}_1 \)-factor \( P \). They show that certain properties of the resulting subfactors (finite depth, respectively, amenability) are precisely mirrored by properties of the subgroup of \( \text{Out}(P) \) generated by \( H \) and \( G \). They also show that the inclusion \( P^H \subseteq P \rtimes G \) is irreducible if and only if \( G \) and \( H \) intersect trivially in \( \text{Out}(P) \).

Specifically, as stated in the abstract, we prove in this paper that if \( \alpha \) and \( \beta \) are actions of groups \( G \) and \( H \) on a unital simple \( C^* \)-algebra \( A \), and if \( H \) is finite, then the inclusion \( A^H \subseteq A \rtimes_r G \) is \( C^* \)-irreducible if and only if \( \alpha_s \circ \beta_t \) is outer for all \((s, t) \in G \times H \) with \((s, t) \neq (e_G, e_H)\). This condition is an exact translation to the realm of \( C^* \)-algebras of the Bisch–Haagerup condition ensuring irreducibility in the subfactor case. In the case where \( H \) is abelian and the two actions \( \alpha \) and \( \beta \) commute, we further establish a Galois correspondence between intermediate \( C^* \)-algebras of the inclusion \( A^H \subseteq A \rtimes_r G \) and subgroups of \( \hat{H} \times G \), where \( \hat{H} \) denotes the Pontryagin dual of \( H \). Clearly, \( A \) itself is an intermediate \( C^* \)-algebra of this inclusion.

We apply our results to some well-known outer actions of finite and infinite cyclic groups on the irrational rotation \( C^* \)-algebra \( A \). There is a canonical (outer) action of the group \( \text{SL}(2, \mathbb{Z}) \) on \( A_\theta \). It is known that \( \mathbb{Z}_2, \mathbb{Z}_3, \mathbb{Z}_4 \) and \( \mathbb{Z}_6 \) are finite cyclic subgroups of \( \text{SL}(2, \mathbb{Z}) \), and in fact the only ones, up to conjugacy. The corresponding actions of these finite cyclic groups on \( A_\theta \) were studied in [8], and it was shown therein, that the fixed-point algebra and the crossed product of \( A_\theta \) by each of these groups gives rise to a simple AF-algebra. We use this, and our main result stated above, to show that if \( F_1 \) and \( F_2 \) are (certain) combinations of the groups \( \mathbb{Z}_2, \mathbb{Z}_3 \) and \( \mathbb{Z}_4 \), then \( A^{F_1}_\theta \subseteq A_\theta \rtimes F_2 \) is a \( C^* \)-irreducible inclusion of simple AF-algebras admitting a non-AF intermediate \( C^* \)-algebra, namely \( A_\theta \). This answers in the negative Question 6.11 from [13]. We also study several interesting examples of \( C^* \)-irreducible inclusions which involve actions of the integer group \( \mathbb{Z} \).

The paper is organized as follows. In Section 2, we collect some well-known and some new results about outer actions of groups on \( C^* \)-algebras. In Section 3, we prove our main result on \( C^* \)-irreducibility of inclusions of the form \( A^H \subseteq A \rtimes_r G \), and in Section 4, we establish the Galois correspondence for the intermediate subalgebras of these inclusions (under the assumptions stated above). Finally, in Section 5, we provide examples of our main results relating to actions on the irrational rotation \( C^* \)-algebras.

2. Outer actions on fixed-point algebras

In this section, we derive some preliminary results on outer actions of a discrete group \( G \) on a \( C^* \)-algebra \( A \). The \( C^* \)-algebra \( A \) may or may not be unital, and if it is not unital, we shall consider its multiplier algebra \( M(A) \). For a unital \( C^* \)-algebra \( A \), we let \( U(A) \) denote its group of unitary elements.
We shall repeatedly use the classic result by Kishimoto from [11, Theorem 3.1] mentioned in the introduction that if $\alpha: G \to \text{Aut}(A)$ is an action of a discrete group $G$ by outer automorphisms on a simple $C^*$-algebra $A$, then the reduced crossed product $A \rtimes_{\alpha,r} G$ is simple as well. We shall often write $A \rtimes_{\alpha} G$ instead of $A \rtimes_{\alpha,r} G$ if $G$ is known to be amenable (in particular, if $G$ is abelian or finite), since then the full and reduced crossed products coincide. Also, we may write $A \rtimes_r G$ instead of $A \rtimes_{\alpha,r} G$ if the action $\alpha$ is understood.

Recall that if $G$ is discrete, there is always a canonical inclusion $A \subseteq A \rtimes_{\alpha,r} G$ together with a canonical unitary representation $u: G \to UM(A \rtimes_{\alpha,r} G)$ implementing the action $\alpha$, i.e., $\alpha_g = \text{Ad} u_g$ for $g \in G$. The algebraic crossed product

$$A \rtimes_{\alpha,\text{alg}} G := \left\{ \sum_{g \in G} a_g u_g : a_g \in A, a_g = 0 \text{ for all but finitely many } g \right\}$$

becomes a dense subalgebra of $A \rtimes_{\alpha,r} G$, and the two algebras coincide if $G$ is finite.

Recall that an action $\alpha$ is outer if no $\alpha_g$ is inner, for $g \neq e$, that is $\alpha_g \neq \text{Ad} v$ for all unitaries $v \in M(A)$. On the other extreme, if the action $\alpha: G \to \text{Aut}(A)$ is implemented by a unitary representation $v: G \to UM(A)$ such that $\alpha_g = \text{Ad} v_g$, for all $g \in G$, we have

$$A \rtimes_{\alpha,r} G \cong A \rtimes_{\text{id},r} G \cong A \otimes C^*_r(G),$$

where the first isomorphism is the extension of the map

$$A \rtimes_{\alpha,\text{alg}} G \to A \rtimes_{\text{id},\text{alg}} G: a_g u_g \mapsto (a_g v_g) u_g.$$

We use these results to prove

**Lemma 2.1.** Let $\alpha: G \to \text{Aut}(A)$ be an action of a discrete group on a simple $C^*$-algebra $A$. Then the following are equivalent:

(i) The action $\alpha$ is outer.

(ii) For all subgroups $H$ of $G$, the crossed product $A \rtimes_{\alpha,r} H$ is simple.

(iii) For all (finite or infinite) cyclic subgroups $C_g := \langle g \rangle$ of $G$, the crossed product $A \rtimes_{\alpha} C_g$ is simple.

**Proof.** The implication (i) $\Rightarrow$ (ii) is a direct consequence of Kishimoto’s theorem, since outerness of $\alpha$ implies outerness of the restriction of $\alpha$ to any subgroup of $G$. The implication (ii) $\Rightarrow$ (iii) is trivial. Thus it suffices to prove (iii) $\Rightarrow$ (i).

So assume that (iii) holds for all $g \in G$. If $\alpha$ is not outer, there exists an element $e \neq g \in G$ such that $\alpha_g(a) = \text{Ad} u(a) = uau^*$ for some unitary element $u \in M(A)$. Let $C_g$ be the cyclic subgroup of $G$ generated by $g$. Suppose first that $g$ has infinite order. Since $\alpha_g^n = \text{Ad} u^n$ for all $n \in \mathbb{Z}$, it follows that the restriction of $\alpha$ to $C_g \cong \mathbb{Z}$ is implemented by the unitary representation $n \mapsto u^n \in UM(A)$, and hence we get

$$A \rtimes_{\alpha} C_g \cong A \otimes C^*(C_g) \cong A \otimes C^*(\mathbb{Z}) \cong A \otimes C(\mathbb{T}),$$

which is certainly not simple.
On the other hand, if $C_g$ is cyclic of order $m \in \mathbb{N}$, then $\text{Ad} u^m = \alpha_e = \text{id}_A$. It follows from simplicity of $A$ that $A' \cap M(A) = \mathbb{C}$, so there must exists $\omega \in \mathbb{T}$ such that $u^m = u^1$. Now, if $\eta \in \mathbb{T}$ is an $m$-th root of $\bar{w}$, we see that $g^k \mapsto (\eta u)^k \in UM(A)$ implements a homomorphism $\bar{u}: C_g \to UM(A)$ such that $\alpha|_{C_g} = \text{Ad} \bar{u}$, and hence

$$A \rtimes_{\alpha} C_g \cong A \otimes C^*(C_g) \cong A \otimes \mathbb{C}^m,$$

which is not simple. \hfill \blacksquare

**Remark 2.2.** In general, outerness for an action $\alpha: G \to \text{Aut}(A)$ on a simple $C^*$-algebra $A$ (unital or not) is not equivalent to $A \rtimes_{\alpha,r} G$ being simple, even if $G$ is finite and abelian and $A$ is simple and unital. To construct a counterexample, let $H$ be any finite abelian group. Let $G := H \times \hat{H}$ be the direct product of $H$ with its dual group $\hat{H}$. For each pair $(g, x) \in H \times \hat{H}$, let $V_{(g,x)}$ be the unitary operator on $\ell^2(H)$ defined by

$$(V_{(g,x)} \xi)(h) = \overline{\langle h, x \rangle} \xi(g^{-1} h),$$

where $\langle \cdot, \cdot \rangle: H \times \hat{H} \to \mathbb{T}$ denotes the canonical pairing between $H$ and $\hat{H}$. A short computation then shows that $V: H \times \hat{H} \to U(\ell^2(H))$ is a projective representation such that

$$V_{(g_1,x_1)} V_{(g_2,x_2)} = \langle g_1, x_2 \rangle V_{(g_1g_2,x_1x_2)}$$

for all $(g_1, x_1), (g_2, x_2) \in H \times \hat{H}$. Thus, $V$ is an $\omega$-representation of the Heisenberg-type 2-cocycle $\omega: H \times \hat{H} \to \mathbb{T}$ defined by $\omega((g_1, x_1), (g_2, x_2)) = \langle g_1, x_2 \rangle$. Let $C^*(H \times \hat{H}, \omega)$ denote the twisted group algebra of $H \times \hat{H}$ with respect to the cocycle $\omega$ (see, e.g., [5, Section 2.8.6] for the construction). Since $\omega$ is totally skew in the sense of [1, p. 300] it follows from [1, Theorem 3.3] that $V$ is the unique irreducible $\omega$-representation of $H \times \hat{H}$, which then implements an isomorphism $C^*(H \times \hat{H}, \omega) \cong B(\ell^2(H)) \cong M|_H(M(\mathbb{C})$.

Now let $A := B(\ell^2(H))$ and define $\beta: H \times \hat{H} \to \text{Aut}(A)$ by $\beta_{(g,x)} = \text{Ad} V_{(g,x)}$. Then one checks that $A \otimes C^*(H \times \hat{H}, \omega)$ is isomorphic to $A \rtimes_{\beta} (H \times \hat{H})$ via the map $a \otimes \delta_{(g,x)} \mapsto a V_{(g,x)} u_{(g,x)}$ (see, e.g., [5, Remark 2.8.18]). Thus $\beta$ is an action by inner automorphisms on the simple unital $C^*$-algebra $A = M|_H(M(\mathbb{C})$ for which $A \rtimes_{\beta} (H \times \hat{H}) \cong M|_H(M(\mathbb{C}) \otimes M|_H(M(\mathbb{C})$ is simple.

### 3. $C^*$-irreducible inclusions arising from fixed-point algebras into crossed products

We shall here prove our main results regarding $C^*$-irreducibility of inclusions arising from fixed-point algebras into crossed products. Let $H$ be a finite group and let $\beta: H \to \text{Aut}(A)$ be an action of $H$ on the $C^*$-algebra $A$. Let

$$A^{H,\beta} := \{ a \in A: \beta_h(a) = a \text{ for all } h \in H \}$$
(or simply $A^H$ if confusion seems unlikely) be the fixed-point algebra of $\beta$. Consider the projection
\[ p^\beta := \frac{1}{|H|} \sum_{h \in H} u_h \in M(A \rtimes_\beta H), \tag{1} \]
where $u: H \to UM(A \rtimes_\beta H)$ denotes the canonical unitary representation which implements $\beta$ in the crossed-product. Note that $p^\beta$ commutes with $A^H$. Rosenberg observed in [14] that the image of the *-homomorphism $A^H \ni a \mapsto ap^\beta = \frac{1}{|H|} \sum_{h \in H} au_h \in A \rtimes_\beta H$ is equal to $p^\beta (A \rtimes_\beta H)p^\beta$, so that we get an isomorphism
\[ A^H \cong p^\beta (A \rtimes_\beta H) p^\beta. \tag{2} \]

We say that $\beta$ is saturated if $Ap^\beta A$ (or $p^\beta$, if $A$ is unital) is full in $A \rtimes_\beta H$, i.e., not contained in any proper closed two-sided ideal in $A \rtimes_\beta H$. Of course, this always holds if the crossed product $A \rtimes_\beta H$ is simple. The following result is then a direct consequence of [10, Corollary 6.6].

**Theorem 3.1** (Izumi). Let $\beta: H \to \text{Aut}(A)$ be an outer action of a finite group $H$ on a unital $C^*$-algebra $A$. Then the inclusion $A^H,\beta \subseteq A$ is $C^*$-irreducible, and the intermediate algebras of the inclusion are precisely the fixed-point algebras $A^{L,\beta}$ for the subgroups $L \subseteq H$.

The following lemma is a modification of [11, Lemma 3.2] by Kishimoto. We are grateful to Masaki Izumi for pointing out to us a modification of our original argument which assumed, in addition to the assumptions given in the lemma, that $\alpha_j$ commutes with $\beta_t$ for all $1 \leq j \leq n$ and $t \in H$.

**Lemma 3.2.** Let $A$ be a unital simple $C^*$-algebra, let $\beta: H \to \text{Aut}(A)$ be an action of a finite group $H$ on $A$. Let $\alpha_1, \ldots, \alpha_n$ be automorphisms of $A$, and let $a_1, \ldots, a_n \in A$ and $\varepsilon > 0$ be given. Suppose that $\alpha_j \circ \beta_t$ is outer on $A$ for all $1 \leq j \leq n$ and for all $t \in H$. Then there exists a positive element $h \in A^H$ with $\|h\| = 1$ such that $\|ha_j\alpha_j(h)\| \leq \varepsilon$ for all $j = 1, \ldots, n$.

**Proof.** First observe that $\alpha_j \circ \beta_t$ is outer for all $t \in H$ implies that $\beta_{s^{-1}} \circ \alpha_j \circ \beta_t$ is outer as well for all $s, t \in H$, which follows from the fact that the conjugate of an outer automorphism by an arbitrary automorphism remains outer.

It follows then from [11, Lemma 3.2] that there exists a positive element $h_0 \in A$ with $\|h_0\| = 1$ and
\[ \|h_0\beta_{s^{-1}}(a_j)(\beta_{s^{-1}} \circ \alpha_j \circ \beta_t)(h_0)\| \leq \varepsilon |H|^{-2}, \quad s, t \in H, \quad 1 \leq j \leq n. \]

Applying the automorphism $\beta_s$ to the inequality above, we obtain that
\[ \|\beta_s(h_0)a_j\alpha_j(\beta_t(h_0))\| \leq \varepsilon |H|^{-2} \]
for all \( s, t \in H \) and for all \( j = 1, 2, \ldots, n \). Set \( h_1 = |H|^{-1} \sum_{s \in H} \beta_s(h_0) \). Then \( h_1 \) is a positive element in \( A^H \), and

\[
\|h_1 a_j \alpha_j(h_1)\| \leq |H|^{-2} \sum_{s, t \in H} \|\beta_s(h_0) a_j \alpha_j(\beta_t(h_0))\| \leq \varepsilon |H|^{-2}.
\]

Since \( \|h_1\| \geq |H|^{-1} \|h_0\| = |H|^{-1} \), it follows that \( h := \|h_1\|^{-1} h_1 \) has the desired properties. \( \blacksquare \)

We proceed to state our first main result characterizing when inclusions of the form \( A^H, G \subseteq A \times_{\alpha, r} G \) are \( C^* \)-irreducible. Thanks to some very helpful comments by Izumi, we can now state this theorem in a stronger form than in a previous version of this paper, where it was assumed that the actions \( \alpha \) and \( \beta \) commute and that the group \( H \) is abelian.

**Theorem 3.3.** Let \( A \) be a unital, simple \( C^* \)-algebra, and let \( \alpha : G \to \text{Aut}(A) \) and \( \beta : H \to \text{Aut}(A) \) be actions of a discrete group \( G \) and a finite group \( H \). Then the following are equivalent:

1. \( A^H, G \subseteq A \times_{\alpha, r} G \) is \( C^* \)-irreducible,
2. \((A^H, G)' \cap (A \times_{\alpha, r} G) = \mathbb{C}\),
3. the automorphisms \( \alpha_g \circ \beta_t \) are outer for all \((e_G, e_H) \neq (g, t) \in G \times H\).

**Proof.** (i) \( \Rightarrow \) (ii) follows from [13, Remark 3.8].

(ii) \( \Rightarrow \) (iii). Suppose that \( \alpha_g \circ \beta_t \) is inner for some \((e_G, e_H) \neq (g, t) \in G \times H\). Then there is a unitary \( u \in A \) such that \( \beta_t = \alpha_{g^{-1}} \circ \text{Ad} u = \text{Ad} u_{g^{-1}} \) (where \( g \mapsto u_g \in A \times_{\alpha, r} G \) is the unitary implementation of \( \alpha \)). Hence \( u_{g^{-1}} u \in (A^H)' \cap (A \times_{\alpha, r} G) \), and \( u_{g^{-1}} u \notin \mathbb{C} \) since \( u \) belongs to \( A \) and \( u_{g^{-1}} \) does not.

(iii) \( \Rightarrow \) (i). Let \( x \) be a non-zero positive element in \( A \times_{\alpha, r} G \). We show that \( x \) is full relative to \( A^H \) in the sense of [13, Definition 3.4]. It follows then from [13, Proposition 3.7] that \( A^H \subseteq A \times_{\alpha, r} G \) is \( C^* \)-irreducible.

Let \( E : A \times_{\alpha, r} G \to A \) be the canonical conditional expectation. Then \( E(x) \in A \) is non-zero and positive. Since \( A^H \subseteq A \) is \( C^* \)-irreducible by Theorem 3.1 (Izumi), it follows from [13, Proposition 3.7 and Lemma 3.5] that there exist \( b_1, \ldots, b_n \in A^H \) such that \( 1_{A^H} \leq \sum_{j=1}^n b_j^* E(x) b_j = \sum_{j=1}^n E(b_j^* x b_j) \). Upon replacing \( x \) by the non-zero positive element \( \sum_{j=1}^n b_j^* x b_j \), we may therefore assume that \( E(x) \geq 1_{A^H} \).

Let \( 0 < \varepsilon < 1 \) be given. Choose \( y = \sum_{g \in G} a_g u_g \in A \times_{\text{alg}} G \) such that \( \|x - y\| < \varepsilon/3 \). According to Lemma 3.2, we can find a positive element \( h \in A^H \) with \( \|h\| = 1 \) such that \( \|h(y - E(y))h\| \leq \varepsilon/3 \). This implies that \( \|h(x - E(x))h\| \leq \varepsilon \). Note that

\[
hxh \geq hE(x)h - \varepsilon \cdot 1_{A^H} \geq h^2 - \varepsilon \cdot 1_{A^H},
\]

so \( h^2 x h^2 \geq h^4 - \varepsilon h^2 \). Let \( \varphi : [0, 1] \to \mathbb{R}^+ \) be a continuous function which vanishes on \([0, \sqrt{\varepsilon}]\) and which is non-zero on \((\sqrt{\varepsilon}, 1]\). Then \( d := \varphi(h)(h^4 - \varepsilon h^2) \varphi(h) \) is non-zero and \( \varphi(h)h^2 x h^2 \varphi(h) \geq d > 0 \). By simplicity of \( A^H \), which follows from outerness of \( \beta \),
Inclusions of \( C^* \)-algebras arising from fixed-point algebras

It follows that
\[
\sum_{j=1}^{n} b_j^* \varphi(h) h^2 x h^2 \varphi(h) b_j \geq \sum_{j=1}^{n} b_j^* d b_j = 1_{A^H}.
\]

which proves that \( x \) is full relative to \( A^H \).

Remark 3.4. It follows from [10, Theorem 3.3] by Izumi that an inclusion \( B \subseteq A \) of simple unital \( C^* \)-algebras with a conditional expectation \( E: A \to B \) of finite index is \( C^* \)-irreducible if (and only if) it is irreducible (i.e., \( A \cap B' = \mathbb{C} \)). The inclusions \( A^{H,\beta} \subseteq A \rtimes_{\alpha,r} G \) considered in Theorem 3.3 do have finite index with respect to the composition of the canonical conditional expectations \( E_1: A \rtimes_{\alpha,r} G \to A \) and \( E_2: A \to A^{H,\beta} \) provided that \( G \) is finite. Hence the implication (ii) \( \Rightarrow \) (i) of Theorem 3.3 is a consequence of Izumi’s theorem when \( G \) is finite. Note that our proof of Theorem 3.3 does not factor through Izumi’s theorem.

Remark 3.5. Condition (iii) of Theorem 3.3 is equivalent to saying that the actions
\[
\alpha: G \to \text{Aut}(A) \quad \text{and} \quad \beta: H \to \text{Aut}(A)
\]
are outer, so that \( G \) and \( H \) may be identified with subgroups of \( \text{Out}(A) \), the outer automorphisms on \( A \), and that \( G \) and \( H \) intersect trivially in \( \text{Out}(A) \). This condition is identical with the condition in [2, Corollary 4.1 (i)] of Bisch and Haagerup ensuring irreducibility of an inclusion \( P^H \subseteq P \rtimes G \) of \( \text{II}_1 \)-factors arising from finite groups \( G \) and \( H \) acting outerly on a \( \text{II}_1 \)-factor \( P \).

4. A Galois correspondence for the intermediate subalgebras

In this section, we shall establish a Galois type classification of the intermediate subalgebras of the inclusions considered in Theorem 3.3 under the additional assumptions that the two actions \( \alpha \) and \( \beta \) commute and that \( H \) is abelian.

Let us first recall that if \( \alpha: G \to \text{Aut}(A) \) and \( \beta: H \to \text{Aut}(A) \) are outer actions on a simple unital \( C^* \)-algebra \( A \) with \( G \) discrete and \( H \) finite, then the intermediate algebras of the inclusions \( A^{H,\beta} \subseteq A \) and \( A \subseteq A \rtimes_{\alpha,r} G \) are in one-to-one correspondence with subgroups \( L \subseteq H \) and \( K \subseteq G \) by taking the fixed-point algebras \( A^L,\beta \) and the crossed products \( A \rtimes_{\alpha,r} K \), respectively, as shown by Izumi [10], and Cameron–Smith [4].

At present time, it is not clear to us how one can describe all intermediate algebras of an inclusion \( A^{H,\beta} \subseteq A \rtimes_{\alpha,r} G \) in the general setting of Theorem 3.3, but we can give a satisfactory answer in the case where \( H \) is abelian and the actions \( \alpha \) and \( \beta \) commute. Note that in the abelian case, there is a bijection between subgroups \( L \) of \( H \) and subgroups of the Pontryagin dual \( \hat{H} = \text{Hom}(H, \mathbb{T}) \) given by \( L \mapsto L^\perp \), where
\[
L^\perp := \{ x \in \hat{H}: \langle \ell, x \rangle = 1 \text{ for all } \ell \in L \}.
\]
Suppose now that $\alpha: G \to \text{Aut}(A)$ and $\beta: H \to \text{Aut}(A)$ are commuting actions of discrete groups $G$ and $H$ on a simple $C^*$-algebra $A$. Then we get an action

$$\alpha \times \beta: G \times H \to \text{Aut}(A), \quad (\alpha \times \beta)_{(g,h)} := \alpha_g \circ \beta_h, \quad (g,h) \in G \times H.$$ 

We shall more than once use the fact that if $\alpha$ and $\beta$ are commuting actions as above, then $\beta$ extends naturally to an action $\tilde{\beta}$ on $A \rtimes_{\alpha,r} G$ given, for $h \in H$ and $\sum_{g \in G} a_g u_g \in A \rtimes_{\alpha,\text{alg}} G$, by

$$\tilde{\beta}_h \left( \sum_{g \in G} a_g u_g \right) = \sum_{g \in G} \beta_h(a_g) u_g.$$

The following lemma is well known to experts (e.g., see [7, Lemma 2.9], where a more general result is shown for full crossed products). For completeness, we include the easy proof.

**Lemma 4.1.** Suppose that $\alpha \times \beta: G \times H \to \text{Aut}(A)$ is an action of the discrete product group $G \times H$, as above, where $H$ is finite. Suppose further that $\beta: H \to \text{Aut}(A)$ is saturated. Then the following hold:

(i) the fixed-point algebra $A^{H,\beta}$ is a $G$-invariant subalgebra of $A$, and $\alpha$ therefore restricts to a well-defined action $\alpha^H: G \to \text{Aut}(A^{H,\beta})$;

(ii) the natural extension of $\beta$ to $\tilde{\beta}: H \to \text{Aut}(A \rtimes_{\alpha,r} G)$ is also saturated;

(iii) the canonical inclusion $A^{H,\beta} \rtimes_{\alpha,r} G \hookrightarrow A \rtimes_{\alpha,r} G$ co-restricts to an isomorphism

$$A^{H,\beta} \rtimes_{\alpha,r} G \cong (A \rtimes_{\alpha,r} G)^{H,\tilde{\beta}}.$$

**Proof.** The first assertion is a direct consequence of the fact that $\alpha$ and $\beta$ commute. For the proof of (ii), we first observe that the canonical inclusion

$$A \rtimes_{\beta} H \hookrightarrow (A \rtimes_{\beta} H) \rtimes_{\tilde{\alpha},r} G \cong (A \rtimes_{\alpha,r} G) \rtimes_{\tilde{\beta}} H$$

maps the projection $p^\beta \in M(A \rtimes_{\beta} H)$ to the projection $p^\tilde{\beta}$ in the multiplier algebra $M((A \rtimes_{\alpha,r} G) \rtimes_{\tilde{\beta}} H)$. Since $p^\beta$ is full in $A \rtimes_{\beta} H$, it follows that

$$(A \rtimes_{\alpha,r} G) \rtimes_{\tilde{\beta}} H = (A \rtimes_{\beta} H) \rtimes_{\tilde{\alpha},r} G$$

$$\cong ((A \rtimes_{\beta} H) p^\beta (A \rtimes_{\beta} H)) \rtimes_{\tilde{\alpha},r} G$$

$$= ((A \rtimes_{\beta} H) \rtimes_{\tilde{\alpha},r} G) p^\beta ((A \rtimes_{\beta} H) \rtimes_{\tilde{\alpha},r} G)$$

$$= ((A \rtimes_{\alpha,r} G) \rtimes_{\tilde{\beta}} H) p^\tilde{\beta} ((A \rtimes_{\alpha,r} G) \rtimes_{\tilde{\beta}} H).$$

Hence $p^\tilde{\beta}$ is full in $(A \rtimes_{\alpha,r} G) \rtimes_{\tilde{\beta}} H$ which proves (ii). The proof of (iii) then follows from

$$(A \rtimes_{\alpha,r} G)^{H,\tilde{\beta}} = p^\tilde{\beta} ((A \rtimes_{\alpha,r} G) \rtimes_{\tilde{\beta}} H) p^\tilde{\beta} = p^\beta ((A \rtimes_{\beta} H) \rtimes_{\tilde{\alpha},r} G) p^\beta = (p^\beta (A \rtimes_{\beta} H) p^\beta) \rtimes_{\tilde{\alpha},r} G = A^{H,\beta} \rtimes_{\alpha,r} G.$$
where the first and the last isomorphism in the above computation follow from Rosenberg’s equation (2).

Using the above observation, we can now prove the following assertion.

**Proposition 4.2.** Let $\alpha$ and $\beta$ be commuting actions of discrete groups $G$ and $H$ on a simple $C^*$-algebra $A$, with $H$ finite, as above. Suppose further that $\alpha \times \beta : G \times H \to \text{Aut}(A)$ is outer. Then the restricted action $\alpha^H : G \to \text{Aut}(A^{H,\beta})$ on the fixed-point algebra $A^{H,\beta}$ is outer.

**Proof.** Let $\alpha \times \beta : G \times H \to \text{Aut}(A)$ be as above. Since $A$ is simple and $\beta$ is outer, it follows from Kishimoto’s theorem that $A \rtimes _\beta H$ is simple as well. Hence $\beta$ is saturated and $A^{H,\beta}$ is a full corner of $A \rtimes _\beta H$ by the full projection $p^\beta$. Since full corners of simple $C^*$-algebras are simple, it follows that $A^{H,\beta}$ is simple.

Thus, by Lemma 2.1, it suffices to show that for every subgroup $M \subseteq G$ the crossed product $A^H \rtimes _\alpha H, r M$ is simple. But it follows from Lemma 4.1 that $A^H \rtimes _\alpha H, r M \cong A^{H,\beta}$ which is a full corner of $(A \rtimes _\alpha H) \rtimes _\beta H \cong A \rtimes _{\alpha \times \beta}, r (M \times H)$. But the latter is simple, again by Kishimoto’s theorem.

We shall also need the lemma below. Let $\beta : H \to \text{Aut}(A)$ be an action of a discrete abelian group $H$ on a $C^*$-algebra $A$. The dual action $\hat{\beta} : \hat{H} \to \text{Aut}(A \rtimes _\beta H)$ is for $x \in \hat{H}$ and $b = \sum_{h \in H} a_h u_h \in A \rtimes _{\beta, \text{alg}} H$ given by

$$\hat{\beta}_x(b) = \sum_{h \in H} \langle h, x \rangle a_h u_h.$$

Since $\hat{H}$ is a compact abelian group, the subgroup $L^\perp$ of $\hat{H}$, defined in (3), associated with a subgroup $L$ of $H$, is compact as well.

**Lemma 4.3.** Suppose that $\beta : H \to \text{Aut}(A)$ is an action of a discrete abelian group on a $C^*$-algebra $A$ and let $L$ be a subgroup of $H$. Then

$$A \rtimes _\beta L = (A \rtimes _\beta H)^{L^\perp},$$

when $A \rtimes _\beta L$ is viewed as a subalgebra of $A \rtimes _\beta H$.

**Proof.** Let $b = \sum_{l \in L} a_l u_l \in A \rtimes _{\beta, \text{alg}} L$. Then

$$\hat{\beta}_x(b) = \sum_{l \in L} \langle l, x \rangle a_l u_l = \sum_{l \in L} a_l u_l = b$$

for all $x \in L^\perp$, so $b$ lies in $(A \rtimes _\beta H)^{L^\perp}$. This proves that $A \rtimes _\beta L \subseteq (A \rtimes _\beta H)^{L^\perp}$.

To prove the converse inclusion, we make use of the conditional expectation $E : A \rtimes _\beta H \to A \rtimes _\beta L$ given by $E(b) = \int_{L^\perp} \hat{\beta}_x(b) \, dx$, where the integral is with respect to the normalized Haar measure. To see that $E$ indeed maps $A \rtimes _\beta H$ onto $A \rtimes _\beta L$, note first that

$$\int_{L^\perp} \langle h, x \rangle \, dx = \begin{cases} 1 & \text{for } h \in L, \\ 0 & \text{for } h \in H \setminus L. \end{cases}$$
Hence, for \( b = \sum_{h \in H} a_h u_h \in A \rtimes_{\beta, \text{alg}} H \), we have

\[
E(b) = \int_{L^\perp} \widehat{\beta}_x(b) \, dx = \int_{L^\perp} \sum_{h \in H} \langle h, x \rangle a_h u_h \, dx = \sum_{l \in L} a_l u_l \in A \rtimes_{\beta} L.
\]

This shows that the range of \( E \) is contained in \( A \rtimes_{\beta} L \) and that \( E \) is the identity on \( A \rtimes_{\beta} L \). Now, since \( E(b) = b \), whenever \( b \in (A \rtimes_{\beta} H)^{L^\perp} \), we are done.

We now provide an elaboration of the observation by Rosenberg stated in (2) relating the fixed-point algebra to a crossed product. Two inclusions \( B_1 \subseteq A_1 \) and \( B_2 \subseteq A_2 \) of \( C^* \)-algebras are said to be isomorphic if there is a \(*\)-isomorphism \( \phi: A_1 \to A_2 \) with \( \phi(B_1) = B_2 \). Clearly, if \( B_1 \subseteq A_1 \) and \( B_2 \subseteq A_2 \) are isomorphic, and if one of the inclusions is \( C^* \)-irreducible, then so is the other.

**Proposition 4.4.** Let \( \beta \) be an action of a finite abelian group \( H \) on a \( C^* \)-algebra \( A \). Then, with \( p^\beta \in M(A \rtimes_{\beta} H) \) as defined above (2), there is an isomorphism \( \psi: A \to p^\beta (A \rtimes_{\beta} H \rtimes_{\hat{\beta}} \hat{H}) p^\beta \) satisfying \( \psi(A^{H, \beta}) = p^\beta (A \rtimes_{\beta} H) p^\beta \), thus implementing an isomorphism between the two inclusions

\[
A^{H, \beta} \subseteq A \quad \text{and} \quad p^\beta (A \rtimes_{\beta} H) p^\beta \subseteq p^\beta (A \rtimes_{\beta} H \rtimes_{\hat{\beta}} \hat{H}) p^\beta.
\]

Moreover, for each subgroup \( L \subseteq H \), we have \( \psi(A^{L, \beta}) = p^\beta (A \rtimes_{\beta} H \rtimes_{\hat{\beta}} L^\perp) p^\beta \), where \( L^\perp \subseteq \hat{H} \) is the annihilator defined above Lemma 4.3.

**Proof.** Let \( u: H \to UM(A \rtimes_{\beta} H) \) and \( \hat{u}: \hat{H} \to UM(A \rtimes_{\beta} H \rtimes_{\hat{\beta}} \hat{H}) \) denote the canonical representations implementing \( \beta \) and \( \hat{\beta} \), respectively. Let \( \langle \cdot, \cdot \rangle: H \times \hat{H} \to \mathbb{T} \) denote the natural pairing between \( H \) and \( \hat{H} \) as in Remark 2.2.

By the definition of the dual action, \( \hat{u}_x \in A' \cap M(A \rtimes_{\beta} H \rtimes_{\hat{\beta}} \hat{H}) \), for all \( x \in \hat{H} \), and \( \hat{u}_x u_g \hat{u}_x^* = \langle g, x \rangle u_g \), for all \( g \in H \) and \( x \in \hat{H} \).

For each \( g \in H \) and \( x \in \hat{H} \), set

\[
p_x = \frac{1}{|H|} \sum_{g \in H} \langle g, x \rangle u_g, \quad q_g = \frac{1}{|H|} \sum_{x \in \hat{H}} \langle g, x \rangle \hat{u}_x.
\]

(Note that \( |H| = |\hat{H}|. \)) In the notation used above (2), \( p_e = p^\beta \) and \( q_e = p^{\hat{\beta}} \) (where \( e \) denotes the neutral element in both groups). By definition of the dual action and the fact that \( \hat{u} \) implements \( \hat{\beta} \), it follows that

\[
\hat{u}_x u_g \hat{u}_x^* = \hat{\beta}_x(u_g) = \langle g, x \rangle u_g, \quad u_g \hat{u}_x u_g^* = u_g \hat{u}_x u_g \hat{u}_x u_g^* = \langle g, x \rangle \hat{u}_x
\]

for all \( g \in H, x \in \hat{H} \). Together with a variant of equation (4), it is then straightforward to verify that

\[
1 = \sum_{g \in H} q_g = \sum_{x \in \hat{H}} p_x, \quad \hat{u}_x p_e \hat{u}_x^* = p_x, \quad u_g q_e u_g^* = q_g
\]

for all \( g \in H \) and \( x \in \hat{H} \).
Recall from Lemma 4.3 that $A = (A \rtimes_\beta H)^\hat{H}$. By Rosenberg’s result, cf. (2), we have $^*$-isomorphisms

$$
\varphi: A^H \to p_e(A \rtimes_\beta H)p_e, \quad \psi_0: A \to q_e(A \rtimes_\beta H \rtimes_\beta \hat{H})q_e,
$$
given by $\varphi(b) = bp_e = |H|^{-1} \sum_{g \in H} b u_g$ and $\psi_0(a) = a q_e = |H|^{-1} \sum_{x \in \hat{H}} a \hat{u}_x$ for $b \in A^H$ and $a \in A$.

Now, by Takai duality, the two projections $p_e$ and $q_e$ are equivalent in the $C^*$-algebra generated by $\{u_g\}_{g \in H} \cup \{\hat{u}_x\}_{x \in \hat{H}}$ (since this $C^*$-algebra is isomorphic to $M_{|H|}(\mathbb{C})$ and $p_e$ and $q_e$ are minimal projections herein). We can also see this directly as follows: For $x \in \hat{H}$, we have $p_e \hat{u}_x p_e = p_e p_x \hat{u}_x = \delta_{e,x} p_e$, so $p_e q_e p_e = |H|^{-1} p_e$. Similarly, $q_e p_e q_e = |H|^{-1} q_e$. Set $z = |H|^{1/2} p_e q_e$. Then $z^* z = q_e$ and $z z^* = p_e$. Note that $z$ commutes with $A^H$. Define a $^*$-isomorphism

$$
\psi: A \to p_e(A \rtimes_\beta H \rtimes_\beta \hat{H})p_e, \quad \psi(a) = z \psi_0(a) z^* (= |H| p_e a q_e p_e), \quad a \in A. \quad (5)
$$

For $b \in A^H$, we have $\psi(b) = z(b q_e) z^* = b z q_e z^* = bp_e = \varphi(b)$. Hence $\psi(A^H) = \varphi(A^H) = p_e(A \rtimes_\beta H)p_e$, as desired.

Let $L \subseteq H$ be a subgroup. We check that $\psi(A^L) = p_e(A \rtimes_\beta H \rtimes_\beta L^\perp)p_e$, where we view $A \rtimes_\beta H \rtimes_\beta L^\perp$ as a subalgebra of $A \rtimes_\beta H \rtimes_\beta \hat{H}$ in the canonical way. Recall from Lemma 4.3, applied to $\hat{\beta}$ via the isomorphism $H \cong \hat{H}$, which maps $g \in H$ to $(x \mapsto (g, x)) \in \hat{H}$, that

$$
A \rtimes_\beta H \rtimes_\beta L^\perp = (A \rtimes_\beta H \rtimes_\beta \hat{H})^{L,\hat{\beta}}.
$$

Since $p_e \in A \rtimes_\beta H$ is fixed by $\hat{\beta}$, we see that $\hat{\beta}$ restricts to an action on $p_e(A \rtimes_\beta H \rtimes_\beta \hat{H})p_e$. So the result will follow if we can show that the isomorphism $\psi: A \to p_e(A \rtimes_\beta H \rtimes_\beta \hat{H})p_e$ is $\beta\hat{\beta}$ equivariant. To this end observe first that for all $g \in H$, we have

$$
\hat{\beta}_g(q_e) = \frac{1}{|H|} \sum_{x \in \hat{H}} \langle g, x \rangle \hat{u}_x = q_e^{-1} = u_g^* q_e u_g.
$$

Using this and the fact that $p_e$ is fixed by $\hat{\beta}$, we get for all $a \in A$ and $g \in H$

$$
\hat{\beta}_g(\psi(a)) = |H| \hat{\beta}_g(p_e a q_e p_e) = |H| p_e a \hat{\beta}_g(q_e) p_e = |H| p_e a u_g^* q_e u_g p_e = |H| p_e u_g^* p_e = p_e = \psi(\hat{\beta}_g(a)).
$$

where at (*) we have used the fact that $p_e u_g^* = u_g p_e = p_e$ for all $g \in H$, which follows easily from the definition of $p_e$. This finishes the proof.

**Lemma 4.5.** Let $B \subseteq A$ be a unital inclusion of $C^*$-algebras, and let $p \in B$ be a projection. If $B \subseteq A$ is $C^*$-irreducible, then so is $pBp \subseteq pAp$. Conversely, if $p$ is full in $B$ and if $pBp \subseteq pAp$ is $C^*$-irreducible, then $B \subseteq A$ is $C^*$-irreducible as well. Moreover, in this case the assignment $D \mapsto pDp$ gives a bijective correspondence between the intermediate $C^*$-algebras of $B \subseteq A$ and those of $pBp \subseteq pA$. 

Proof. Assume first that $B \subseteq A$ is $C^*$-irreducible. Let $pBp \subseteq C \subseteq pAp$ be an intermediate $C^*$-algebra, and set $D = C^*(B \cup C)$. Then $B \subseteq D \subseteq A$, so $D$ is simple. Moreover, $C = pDp$, so $C$ is a corner of the simple $C^*$-algebra $D$, and is hence simple as well.

Suppose now that $p$ is full and that $pBp \subseteq pAp$ is $C^*$-irreducible. If $B \subseteq D \subseteq A$ is any intermediate $C^*$-algebra, then $pBp \subseteq pDp \subseteq pAp$, and hence $pDp$ is simple. Since $p$ is full in $B$, it follows that $p$ is also full in $D$, and this implies that $D$ is simple.

As for the last claim, we remarked above that the assignment $C \mapsto C^*(B \cup C)$ gives a map from intermediate $C^*$-algebras of the inclusion $pBp \subseteq pAp$ to intermediate $C^*$-algebras of the inclusion $B \subseteq A$, which is a left-inverse of the assignment $D \mapsto pDp$, i.e., $pC^*(B \cup C)p = C$, for any $pBp \subseteq C \subseteq pAp$. If $p$ is full in $B$, then it is also a right-inverse, i.e., $D = C^*(B \cup pDp)$ for any $B \subseteq D \subseteq A$. Indeed, $l = 1 \mapsto \sum^n_{j=1} b_j^* p b_j$ for some $b_1, \ldots, b_n \in B$ by fullness of $p$ in $B$. Hence, for each $d \in D$, we have $d = 1 \cdot d = \sum_{i,j=1}^n b_i^* p b_i d b_j p b_j^*$, which belongs to $C^*(B \cup pDp)$, since $p b_i d b_j p p Dp$, for all $i, j$.

We are now ready to give a Galois type classification of the intermediate subalgebras of (some of) the inclusion $A^{H, \beta} \subseteq A \rtimes_{\alpha, r} G$ considered in Theorem 3.3.

**Theorem 4.6.** Suppose that $\alpha: G \to \text{Aut}(A)$ and $\beta: H \to \text{Aut}(A)$ are commuting actions of a discrete group $G$ and a finite abelian group $H$ on a unital simple $C^*$-algebra $A$.

(i) The inclusion $A^{H, \beta} \subseteq A \rtimes_{\alpha, r} G$ is isomorphic to the inclusion

$$p^\beta(A \rtimes_\beta H)p^\beta \subseteq p^\beta(A \rtimes_\beta H \rtimes_{\tilde{\beta}} \hat{H} \rtimes_{\tilde{\alpha}, r} G)p^\beta,$$

where $p^\beta$ is as defined in (1), and where $\tilde{\alpha}: G \to \text{Aut}(A \rtimes_\beta H \rtimes_{\tilde{\beta}} \hat{H})$ is the extension of $\alpha$, cf. the explanation above Lemma 4.1.

(ii) There is a one-to-one correspondence between subgroups $L \subseteq \hat{H} \times G$ and intermediate algebras of the inclusion in (6) given by sending $L$ to

$$p^\beta(A \rtimes_\beta H)p^\beta \rtimes_{\tilde{\beta} \times_{\tilde{\alpha}, r}} L = p^\beta(A \rtimes_\beta H \rtimes_{\tilde{\beta} \times_{\tilde{\alpha}, r}} L)p^\beta.$$

(iii) There is a one-to-one correspondence between subgroups of $\hat{H} \times G$ and intermediate algebras of the inclusion $A^{H, \beta} \subseteq A \rtimes_{\alpha, r} G$.

In particular, if $L = L_1 \times L_2$ is a product of subgroups $L_1 \subseteq \hat{H}$ and $L_2 \subseteq G$, then the corresponding intermediate algebra $A^{H, \beta} \subseteq D \subseteq A \rtimes_{\alpha, r} G$ is $D = A^{L_1^+, \beta} \rtimes_{\alpha, r} L_2$, with $L_1^+$ the annihilator of $L_1$ in $H$, cf. (3).

Proof. (i) It was shown in Proposition 4.4 that the inclusion $A^H \subseteq A$ is isomorphic to the inclusion $p^\beta(A \rtimes_\beta H)p^\beta \subseteq p^\beta(A \rtimes_\beta H \rtimes_{\tilde{\beta}} \hat{H})p^\beta$ via the *-isomorphism

$$\psi: A \to p^\beta(A \rtimes_\beta H \rtimes_{\tilde{\beta}} \hat{H})p^\beta,$$

defined in (5), that maps $A^H$ onto $p^\beta(A \rtimes_\beta H)p^\beta$. The isomorphism $\psi$ is easily seen to be $\alpha$-$\tilde{\alpha}$ equivariant. Hence it extends naturally to a *-isomorphism $\tilde{\psi}: A \rtimes_{\alpha, r} G \to$
Inclusions of $C^*$-algebras arising from fixed-point algebras

$p^\beta (A \rtimes H \times \bar{\beta} H) p^\beta \rtimes \tilde{\alpha}, r G$. The algebra $p^\beta (A \rtimes H \times \bar{\beta} H) p^\beta \rtimes \tilde{\alpha}, r G$ coincides with $p^\beta (A \rtimes H \times \bar{\beta} H \times \tilde{\alpha}, r G) p^\beta$ because $\tilde{\alpha}_g(p^\beta) = p^\beta$ for all $g \in G$ by the definition of $\tilde{\alpha}$. The $^*$-isomorphism $\psi$ therefore implements the desired isomorphism of the two inclusions.

(ii) Since $A^H \subseteq A \rtimes \alpha, r G$ is $C^*$-irreducible by Theorem 3.3, so is the inclusion in (6), and hence so is the inclusion

$$A \rtimes H \subseteq A \rtimes H \times \bar{\beta} H \times \tilde{\alpha}, r G = A \rtimes H \times \hat{\beta} \times \tilde{\alpha}, r (\hat{H} \times G),$$

by Lemma 4.5. It follows from [13, Theorem 5.8] that $\hat{\beta} \times \tilde{\alpha}: \hat{H} \times G \to \text{Aut}(A \rtimes H)$ is outer.

By Lemma 4.5, there is a bijective correspondence between intermediate $C^*$-algebras of the inclusion in (7) and intermediate $C^*$-algebras of the inclusion in (6) given by compression with $p^\beta$. Finally, by the Cameron–Smith theorem, [4, Theorem 3.5], which applies because $\hat{\beta} \times \tilde{\alpha}$ is outer, each intermediate $C^*$-algebra of the inclusion in (7) is of the form

$$(A \rtimes H) \rtimes \hat{\beta} \times \tilde{\alpha}, r L$$

for some subgroup $L$ of $\hat{H} \times G$. This proves (ii).

(iii) follows from (i) and (ii) and, for the last claim, inspection of the isomorphism $\psi$ which implements the isomorphism of the two inclusions in (i).

5. Examples

In this section, we want to discuss some interesting examples of the theory as developed in the previous sections arising from group actions on the irrational rotation algebra $A_{\theta}$ for $\theta \in \mathbb{R} \setminus \mathbb{Q}$. Recall that $A_{\theta}$ is the universal $C^*$-algebra generated by two unitaries $u, v$ subject to the relation

$$vu = e^{2\pi i \theta} uv.$$

There is an outer action $\alpha: \text{SL}(2, \mathbb{Z}) \to \text{Aut}(A_{\theta})$ for which

$$n = \begin{pmatrix} n_{11} & n_{12} \\ n_{21} & n_{22} \end{pmatrix} \in \text{SL}(2, \mathbb{Z})$$

acts on the generators $u, v$ of $A_{\theta}$ by

$$\alpha_n(u) = e^{2\pi i n_{12} \theta} u, \quad \alpha_n(v) = e^{2\pi i n_{11} \theta} v.$$

Up to conjugacy, there are exactly four different finite cyclic subgroups of $\text{SL}(2, \mathbb{Z})$ isomorphic to the cyclic groups $\mathbb{Z}_2, \mathbb{Z}_3, \mathbb{Z}_4, \text{and } \mathbb{Z}_6$, generated, in that order, by the elements

$$\begin{pmatrix} -1 & 0 \\ 0 & -1 \end{pmatrix}, \quad \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}, \quad \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}, \quad \begin{pmatrix} 0 & -1 \\ 1 & 1 \end{pmatrix}. \quad (8)$$
The resulting crossed products $A_\theta \rtimes_{\alpha} \mathbb{Z}_k$, $k = 2, 3, 4, 6$, have been studied in detail in [8], where it has been shown that they, as well as the fixed-point algebras $A_\theta^{\mathbb{Z}_k}$, $k = 2, 3, 4, 6$, are simple AF-algebras. By [13, Theorem 5.8], all inclusions $A_\theta \subseteq A_\theta \rtimes_{\alpha} \mathbb{Z}_k$ are $C^*$-irreducible, and it follows from Theorem 3.1 (Izumi) that the inclusions $A_\theta^{\mathbb{Z}_k} \subseteq A_\theta$ are $C^*$-irreducible as well. Thus we see that every $A_\theta$, with $\theta$ irrational, has a unital $C^*$-irreducible inclusion into some simple AF-algebra, and that, on the other hand, there always exist simple AF-algebras which admit a unital $C^*$-irreducible embedding into $A_\theta$. But note that the composition $A_\theta \rtimes_{\alpha} \mathbb{Z}_k$ of these inclusions is not $C^*$-irreducible, since $A_\theta G / 0 \not\subseteq A_\theta \rtimes_{\alpha} G / C$; as observed earlier for general actions $\alpha: G \to \text{Aut}(A)$ of a finite group $G$. On the other hand, since the entire group $\text{SL}(2, \mathbb{Z})$ acts by outer automorphisms on $A_\theta$, condition (iii) of Theorem 3.3 is satisfied for the actions of two subgroups $F_1, F_2 \subseteq \text{SL}(2, \mathbb{Z})$ on $A_\theta$ if and only if their intersection $F_1 \cap F_2$ is trivial in $\text{SL}(2, \mathbb{Z})$. We therefore get the following proposition.

**Proposition 5.1.** Suppose that $(F_1, F_2)$ is either one of the pairs

$$(\mathbb{Z}_2, \mathbb{Z}_3), \quad (\mathbb{Z}_3, \mathbb{Z}_4), \quad (\mathbb{Z}_3, \mathbb{Z}_3),$$

where $\mathbb{Z}_3 := \langle R \rangle$ for some matrix $R \in \text{SL}(2, \mathbb{Z})$ which is a conjugate of the matrix $\begin{pmatrix} 0 & 1 \\ -1 & -1 \end{pmatrix}$ inside $\text{SL}(2, \mathbb{Z})$ and for which $\mathbb{Z}_3 \cap \mathbb{Z}_3 = 1$.\footnote{One can, for example, take $R = \begin{pmatrix} -2 & 1 \\ 3 & 1 \end{pmatrix} = S \begin{pmatrix} 0 & 1 \\ -1 & -1 \end{pmatrix} S^{-1}$ with $S = \begin{pmatrix} 1 & 1 \\ 1 & 1 \end{pmatrix}$.} Then

$$A_{\theta}^{F_1} \subseteq A_\theta \rtimes F_2, \quad A_{\theta}^{F_2} \subseteq A_\theta \rtimes F_1$$

are $C^*$-irreducible inclusions of AF-algebras.

**Proof.** In all these cases, we have $F_1 \cap F_2 = 1$ in $\text{SL}(2, \mathbb{Z})$, so the result follows from Theorem 3.3.

Among the finite subgroups of $\text{SL}(2, \mathbb{Z})$ listed in and above (8), the pairs $(F_1, F_2)$ listed in the proposition above are the only ones which satisfy item (iii) of Theorem 3.3, so any other combination of subgroups $(F_1, F_2)$ will not provide $C^*$-irreducible inclusions. Since $A_\theta$ is not an AF-algebra, Proposition 5.1 leads (as expected) to a negative answer to [13, Question 6.11].

**Corollary 5.2.** There exist $C^*$-irreducible inclusions of AF-algebras with intermediate $C^*$-algebras that are not AF-algebras.

Of the three pairs of groups $(F_1, F_2)$ in Proposition 5.1 above, only the pair $(\mathbb{Z}_2, \mathbb{Z}_3)$ satisfies the additional assumptions of Theorem 4.6 which gives a classification of the intermediate $C^*$-algebras. This pair also satisfies the conditions of the following.
Proposition 5.3. Suppose that $H$ and $G$ are finite cyclic groups of prime orders $p$ and $q$, respectively, such that $p \neq q$. Let $\alpha \times \beta \colon G \times H \to \text{Aut}(A)$ be an outer action on the simple unital C*-algebra $A$. Then $A^{H,\beta} \subseteq A \rtimes_\alpha G$ is a C*-irreducible inclusion, and $A$ and $A^{H,\beta} \rtimes_\alpha G$ are the only (strict) intermediate C*-algebras for this inclusion.

Proof. Since finite cyclic groups are self-dual, it follows from the assumption on the pair $p$, $q$ that $\hat{H} \cong \hat{H} \times \{e\}$ and $G \cong \{e\} \times G$ are the only non-trivial subgroups of $\hat{H} \times G$. Thus it follows from Theorem 4.6 that $A = A^{\hat{H},\beta}$ and $A^{H,\beta} \rtimes_\alpha G = A^{\{e\},\beta} \rtimes_\alpha G$ are the only strict intermediate C*-algebras for the inclusion $A^{H,\beta} \subseteq A \rtimes_\alpha G$. □

Corollary 5.4. Let $\theta \in \mathbb{R} \setminus \mathbb{Q}$. The only strict intermediate C*-algebras for the C*-irreducible inclusion $A^Z_{\theta,\alpha} \subseteq A_{\theta} \rtimes_\beta \mathbb{Z}_3$ are $A_{\theta}$ and $A^Z_{\theta,\alpha} \rtimes_\alpha \mathbb{Z}_3$. Similarly, the only strict intermediate C*-algebras for the C*-irreducible inclusion $A^Z_{\theta,\alpha} \subseteq A_{\theta} \rtimes_\alpha \mathbb{Z}_2$ are $A_{\theta}$ and $A^Z_{\theta,\alpha} \rtimes_\alpha \mathbb{Z}_2$.

Note that the intermediate algebras $A^Z_{\theta,\alpha} \rtimes_\beta \mathbb{Z}_3$ and $A^Z_{\theta,\alpha} \rtimes_\alpha \mathbb{Z}_2$ are AF-algebras. Indeed, it is shown in [8] that $A_{\theta} \rtimes_\gamma \mathbb{Z}_6 = A_{\theta} \rtimes_\alpha \beta (\mathbb{Z}_2 \times \mathbb{Z}_3)$ is an AF-algebra. By Lemma 4.1 together with Rosenberg’s isomorphism (2), it follows that

$A^Z_{\theta,\alpha} \rtimes_\beta \mathbb{Z}_3 = (A_{\theta} \rtimes_\beta \mathbb{Z}_3)^Z_{\theta,\alpha}$

is a (full) corner of $A_{\theta} \rtimes_\beta \mathbb{Z}_3 \rtimes_\alpha \mathbb{Z}_2 \cong A_{\theta} \rtimes_\gamma \mathbb{Z}_6$, and similarly for $A^Z_{\theta,\alpha} \rtimes_\alpha \mathbb{Z}_2$. Since corners of AF-algebras are AF-algebras, it follows that $A^Z_{\theta,\alpha} \rtimes_\beta \mathbb{Z}_3$ and $A^Z_{\theta,\alpha} \rtimes_\alpha \mathbb{Z}_2$ are AF-algebras.

Remark 5.5. It would be very interesting also to understand the intermediate C*-algebras of the inclusions appearing in Proposition 5.1, other than the ones arising from the pair $(\mathbb{Z}_2, \mathbb{Z}_3)$.

Perhaps, the most interesting case is given by the inclusion $A^Z_{\theta} \subseteq A_{\theta} \rtimes \tilde{\mathbb{Z}}_3$. The only obvious intermediate C*-algebra here is $A_{\theta}$ itself, and it might well be that it is the only one. (By an “obvious” intermediate C*-algebra of an inclusion $A^H \subseteq A \rtimes_r G$, we think here of one of the form $D \rtimes_{r,\alpha} L$, where $L$ is a subgroup of $G$ and $D$ is an $L$-invariant intermediate algebra $A^H \subseteq D \subseteq A$.) If that would be true it would give us an example of a C*-irreducible inclusion of two AF-algebras with $A_{\theta}$ as the unique intermediate C*-algebra.

Since $\tilde{\mathbb{Z}}_3$ is a conjugate of $\mathbb{Z}_3$ by an element of $\text{SL}(2, \mathbb{Z})$, the crossed product $A_{\theta} \rtimes \tilde{\mathbb{Z}}_3$ is canonically isomorphic to the crossed product $A_{\theta} \rtimes \mathbb{Z}_3$ in which $A^Z_{\theta}$ sits as a full corner. In particular, $A^Z_{\theta}$ and $A_{\theta} \rtimes \tilde{\mathbb{Z}}_3$ are Morita equivalent AF-algebras.

Actions by infinite cyclic groups. Actions on $A_{\theta}$ can provide further examples of C*-irreducible inclusions with interesting properties. For this let us consider actions of $\mathbb{Z}$ on $A_{\theta}$ which are given by restrictions of the action of $\text{SL}(2, \mathbb{Z})$ to infinite cyclic subgroups. These are generated by matrices $S \in \text{SL}(2, \mathbb{Z})$ of infinite order. Let us then write $\alpha^S$ for the corresponding action of $\mathbb{Z}$ on $A_{\theta}$. The crossed products $A_{\theta} \rtimes_{\alpha^S} \mathbb{Z}$ have been studied and classified in [3]. A particularly interesting example occurs if $\text{tr}(S) = 3$, e.g.,
for $S = \left( \begin{array}{cc} 1 & 1 \\ 1 & 2 \end{array} \right)$. In this case, the classification results of [3] imply that $A_\theta \rtimes_{\alpha_S} \mathbb{Z}$ is actually isomorphic to $A_\theta$ itself. Thus by [13, Theorem 5.8] and [4], we obtain a proper $C^*$-irreducible inclusion

$$A_\theta \subseteq A_\theta \rtimes_{\alpha_S} \mathbb{Z} \cong A_\theta.$$ 

By the results of Cameron and Smith [4, Theorem 3.5], all (strict) intermediate $C^*$-algebras are of the form

$$A_\theta \rtimes_{\alpha_S} (n\mathbb{Z}) = A_\theta \rtimes_{\alpha_S^n} \mathbb{Z}, \quad n = 2, 3, 4, \ldots$$

Using the results of [3, Theorem 3.5], all these intermediate algebras can be classified by their Elliott invariants, and it turns out that they are never AF (since by [3, Theorem 3.5] their $K_1$-groups never vanish) and they are usually not isomorphic to $A_\theta$.

**Example 5.6.** Let us look again at the matrix $S = \left( \begin{array}{cc} 1 & 1 \\ 1 & 2 \end{array} \right)$. Then $S$ is self-adjoint with $\text{tr}(S) = 3$. The entries of the powers of $S$ are Fibonacci numbers

$$S^n = \begin{pmatrix} f_{2n-1} & f_{2n} \\ f_{2n} & f_{2n+1} \end{pmatrix}, \quad n \geq 1.$$ 

In particular, it follows that $\text{tr}(S^n) > 3$ for all $n \geq 2$, and hence it follows from [3, Theorems 3.5 and 3.9] that the intermediate algebras $A_\theta \rtimes_{\alpha_S^n} \mathbb{Z}$ of the inclusion $A_\theta \subseteq A_\theta \rtimes_{\alpha_S} \mathbb{Z} \cong A_\theta$ are never isomorphic to $A_\theta$ and are not even irrational rotation algebras.

Indeed, using [3, Remark 3.12], we can conclude that $A_\theta \rtimes_{\alpha_S^n} \mathbb{Z}$ and $A_\theta \rtimes_{\alpha_S^m} \mathbb{Z}$ are never isomorphic if $n \neq m$, since we have $|2 - \text{tr}(S^n)| \neq |2 - \text{tr}(S^m)|$, whenever $n, m \in \mathbb{N}$ with $n \neq m$.

**Remark 5.7.** For any element $S \in \text{SL}(2, \mathbb{Z})$ of infinite order, the intersection $\langle S \rangle \cap F$ is trivial for any finite subgroup $F \subseteq \text{SL}(2, \mathbb{Z})$. Therefore, with $S = \left( \begin{array}{cc} 1 & 1 \\ 1 & 2 \end{array} \right)$ as above, we get $C^*$-irreducible inclusions

$$A_\theta^F \subseteq A_\theta \rtimes_{\alpha_S} \mathbb{Z} \cong A_\theta$$

for every such subgroup $F$. In the case where $F = \mathbb{Z}_2$, which is generated by the central element $\left( \begin{array}{cc} 1 & 0 \\ 0 & 1 \end{array} \right)$, the actions of $F$ and $\mathbb{Z}$ commute and Theorem 4.6 gives a description of all intermediate algebras for this inclusion.

Another interesting consequence of this type of examples is the existence of outer actions $\beta^n$ of the cyclic groups $\mathbb{Z}_n$ on $A_\theta$ for all $n \in \mathbb{N}$ with $n \geq 2$, such that the crossed products $A_\theta \rtimes_{\beta^n} \mathbb{Z}_n$ as well as the fixed-point algebras $A_\theta^{\mathbb{Z}_n, \beta^n}$ are not AF, quite contrary to the case of the actions of the finite subgroups of $\text{SL}(2, \mathbb{Z})$ considered before. For this we need the following lemma.

**Lemma 5.8.** Suppose that $\beta \colon H \to \text{Aut}(A)$ is an outer action of the discrete abelian group $H$ on a simple $C^*$-algebra $A$. Then, for each finite subgroup $M \subseteq \hat{H}$, the restriction of the dual action $\hat{\beta} \colon \hat{H} \to \text{Aut}(A \rtimes_{\beta} H)$ to $M$ is outer as well.
If $\hat{H}$ is finite, or more generally, if $\hat{H}$ has no element of infinite order, then the lemma simply says that $\hat{\beta}$ itself also is outer, cf. Lemma 2.1.

Proof. Let $L \subseteq M \subseteq \hat{H}$ be any subgroup of $M$, and let $L^\perp$ be the annihilator of $L$ in $H$. Then it follows from [6, Proposition 2.1] that $(A \rtimes_{\beta} H) \rtimes_{\hat{\beta}} L$ is Morita equivalent to $A \rtimes_{\beta} L^\perp$, which is simple by Lemma 2.1. Thus, since Morita equivalence preserves simplicity, the crossed product $(A \rtimes_{\beta} H) \rtimes_{\hat{\beta}} L$ is simple as well. Thus, it follows from Lemma 2.1 that the restriction of $\hat{\beta}$ to $M$ is by outer automorphisms. ■

Example 5.9. Let $S = \left( \frac{1}{2} \right)$ as above (for most of what we do here, one could take any $S \in \text{SL}(2, \mathbb{Z})$ with $\text{tr}(S) = 3$). Consider the dual action $\hat{\alpha}^S: \mathbb{T} \to \text{Aut}(A_{\theta} \rtimes_{\alpha} \mathbb{Z})$ of $\alpha^S$. The isomorphism $A_{\theta} \rtimes_{\alpha} \mathbb{Z} \cong A_{\theta}$ carries this to an action, say $\hat{\beta}: \mathbb{T} \to \text{Aut}(A_{\theta})$. For each $n \in \mathbb{N}$, let us identify the cyclic group $\mathbb{Z}_n$ of order $n$ with the group of all $n$-th roots of unity in $\mathbb{T}$, which is the annihilator of $n\mathbb{Z} \subseteq \mathbb{Z}$ under the identification $\mathbb{T} \cong \hat{\mathbb{Z}}$. Thus $\mathbb{Z}_n$ can be identified with $(n\mathbb{Z})^\perp \subseteq \mathbb{T}$. It follows from Lemma 5.8 that the restriction of $\hat{\beta}$ to $\mathbb{Z}_n$ gives an outer action, called $\beta^n$ below, of $\mathbb{Z}_n$ on $A_{\theta}$. Thus, using [13, Theorem 5.8] and Theorem 3.3, we obtain $C^*$-irreducible inclusions

$$A_{\theta}^{\mathbb{Z}_n, \beta^n} \subseteq A_{\theta} \quad \text{and} \quad A_{\theta} \subseteq A_{\theta} \rtimes_{\beta^n} \mathbb{Z}_n$$

with intermediate algebras given by $A_{\theta}^{\mathbb{Z}_m, \beta^m}$ and $A_{\theta} \rtimes_{\beta^m} \mathbb{Z}_m$, respectively, for all $m \in \mathbb{N}$ which divide $n$. It follows then from Lemma 4.3 that

$$A_{\theta}^{\mathbb{Z}_m, \beta^m} \cong A_{\theta} \rtimes_{\alpha^m} \mathbb{Z}.$$ 

So at least for $S = \left( \frac{1}{2} \right)$, it follows from Example 5.6 that the $C^*$-algebras above are pairwise non-isomorphic for different $m$, and that none of them are AF-algebras.

Note, if $n, m \in \mathbb{N}$ have no common divisors, then $\mathbb{Z}_n \cap \mathbb{Z}_m = \{0\}$, and Theorem 3.3 implies that the inclusion

$$A_{\theta}^{\mathbb{Z}_n, \beta^n} \subseteq A_{\theta} \rtimes_{\beta^n} \mathbb{Z}_m$$

is also $C^*$-irreducible. Again, in this case, Theorem 4.6 allows us to compute all intermediate algebras of this inclusion.

Question 5.10. Let $A_{\theta} \subseteq A_{\theta} \rtimes_{\alpha} \mathbb{Z} \cong A_{\theta}$ be the $C^*$-irreducible inclusion considered in Remark 5.7 above. By iteration, we get a chain of inclusions

$$A_{\theta} \subseteq A_{\theta} \subseteq \cdots \subseteq A_{\theta} \subseteq \cdots$$

Are all compositions in this sequence $C^*$-irreducible?

It has been shown in [3, Remark 3.11] that the direct limit of this sequence is the AF-algebra constructed by Effros and Shen in [9], and into which $A_{\theta}$ embeds with the same ordered $K_0$-groups, as shown by Pimsner and Voiculescu in [12].
Acknowledgments. The authors would like to thank Masaki Izumi and Stefaan Vaes for very helpful comments which helped to substantially improve the paper. In particular, we would like to thank Masaki Izumi for pointing out to us the result [10, Corollary 6.6] and a modification of our Lemma 3.2 which resulted in a major improvement of our main results.
