Stimulus collative properties in food products and their importance for consumer liking:  
A case study with novel beers

Introduction  
There is a dilemma between liking for familiar stimuli and a wish to experiment with new ones. Berlyne’s theory on aesthetic preference\(^1\), predicts that to maximize sensory appreciation, a (food) product should aim at optimizing the balance between familiarity and novelty.

Methods  
Eight beers were tested by a consumer panel (N=135), for which relevant consumer characteristics – namely product knowledge, food neophobia and variety seeking tendency – were known. Consumers evaluated liking and three collative properties: novelty, familiarity and complexity.

Results  
A multiple linear regression model was carried out to analyze effects of the three collative properties on liking (Adj. \(R^2 = .4\), \(F_{3,1076} = 239.66, p < .001\)). All properties significantly positively predicted liking, with complexity (\(b = .47\), \(t_{1076} = 14.67, p < .001\)) and familiarity (\(b = .39\), \(t_{1076} = 15.06, p < .001\)) being the strongest regressors, followed by novelty (\(b = .27\), \(t_{1076} = 8.23, p < .001\)). Non-linear relationships were assessed by computing smoothing points using locally weighted polynomial regression\(^2\). Berlyne’s predicted trajectory (inverse U-shaped) described most accurately the relationship between novelty and liking (Figure 1a), whereas the relationships between liking and the two other collative properties is linear and monotonic (Figure 1b+c).

ANOVA was performed using consumer traits as main effects. High variety seeking consumers gave significantly higher overall liking (\(p = .008\)). Consumers with higher product knowledge rated the beers significantly more familiar (\(p = .02\)), less novel (\(p = .03\)) and less complex (\(p < .001\)). No significant effects of degree of neophobia were observed.

Conclusion  
Taken overall, our results confirm that liking is indeed a result from a combination of novelty, familiarity and complexity. Furthermore, we expand prior work on collative properties in a food context, by showing that several different consumer variables need to be taken into consideration for predicting consumer liking.
