RINGS WITH FINITE GORENSTEIN INJECTIVE DIMENSION

HENRIK HOLM

(Communicated by Bernd Ulrich)

Abstract. In this paper we prove that for any associative ring $R$, and for any left $R$-module $M$ with finite projective dimension, the Gorenstein injective dimension $\text{Gid}_R M$ equals the usual injective dimension $\text{id}_R M$. In particular, if $\text{Gid}_R R$ is finite, then also $\text{id}_R R$ is finite, and thus $R$ is Gorenstein (provided that $R$ is commutative and Noetherian).

1. Introduction

It is well known that among the commutative local Noetherian rings $(R, \mathfrak{m}, k)$, the Gorenstein rings are characterized by the condition $\text{id}_R R < \infty$. From the dual of [10, Proposition (2.27)] (5 Proposition 10.2.3] is a special case) it follows that the Gorenstein injective dimension $\text{Gid}_R (-)$ is a refinement of the usual injective dimension $\text{id}_R (-)$ in the following sense:

For any $R$-module $M$ there is an inequality $\text{Gid}_R M \leq \text{id}_R M$, and if $\text{id}_R M < \infty$, then there is an equality $\text{Gid}_R M = \text{id}_R M$.

Now, since the injective dimension $\text{id}_R R$ of $R$ measures Gorensteinness, it is only natural to ask what does the Gorenstein injective dimension $\text{Gid}_R R$ of $R$ measure? As a consequence of Theorem (2.1) below, it turns out that:

An associative ring $R$ with $\text{Gid}_R R < \infty$ also has $\text{id}_R R < \infty$ (and hence $R$ is Gorenstein, provided that $R$ is commutative and Noetherian).

This result is proved by Christensen [2, Theorem (6.3.2)] in the case where $(R, \mathfrak{m}, k)$ is a commutative local Noetherian Cohen-Macaulay ring with a dualizing module. The aim of this paper is to prove Theorem (2.1), together with a series of related results. Among these results is Theorem (3.2), which has the nice, and easily stated, Corollary (3.3):

Assume that $(R, \mathfrak{m}, k)$ is a commutative local Noetherian ring, and let $M$ be an $R$-module of finite depth, that is, $\text{Ext}^{m}_{R}(k, M) \neq 0$ for some $m \in \mathbb{N}_0$ (this happens for example if $M \neq 0$ is finitely generated). If either

$(i)$ $\text{Gid}_R M < \infty$ and $\text{id}_R M < \infty$ \quad or \quad $(ii)$ $\text{fd}_R M < \infty$ and $\text{Gid}_R M < \infty$,

then $R$ is Gorenstein.
This corollary is also proved by Christensen [2, Theorem (6.3.2)] in the case where \((R, m, k)\) is Cohen-Macaulay with a dualizing module. However, Theorem (3.2) itself (dealing not only with local rings) is a generalization of [8, Proposition 2.10] (in the module case) by Foxby from 1979.

We should briefly mention the history of Gorenstein injective, projective and flat modules: Gorenstein injective modules over an arbitrary associative ring, and the related Gorenstein injective dimension, was introduced and studied by Enochs and Jenda in [3]. The dual concept, Gorenstein projective modules, was already introduced by Auslander and Bridger [1] in 1969, but only for finitely generated modules over a two-sided Noetherian ring. Gorenstein flat modules were also introduced by Enochs and Jenda; please see [5].

1.1. Setup and notation. Let \(R\) be any associative ring with a nonzero multiplicative identity. All modules are—if not specified otherwise—left \(R\)-modules. If \(M\) is any \(R\)-module, we use \(\text{pd}_{R}M\), \(\text{fd}_{R}M\), and \(\text{id}_{R}M\) to denote the usual projective, flat, and injective dimension of \(M\), respectively. Furthermore, we write \(\text{Gpd}_{R}M\), \(\text{Gfd}_{R}M\), and \(\text{Gid}_{R}M\) for the Gorenstein projective, Gorenstein flat, and Gorenstein injective dimension of \(M\), respectively.

2. Rings with finite Gorenstein injective dimension

**Theorem 2.1.** If \(M\) is an \(R\)-module with \(\text{pd}_{R}M < \infty\), then \(\text{Gid}_{R}M = \text{id}_{R}M\). In particular, if \(\text{Gid}_{R}R < \infty\), then also \(\text{id}_{R}R < \infty\) (and hence \(R\) is Gorenstein, provided that \(R\) is commutative and Noetherian).

**Proof.** Since \(\text{Gid}_{R}M = \text{id}_{R}M\) always, it suffices to prove that \(\text{id}_{R}M \leq \text{Gid}_{R}M\). Naturally, we may assume that \(\text{Gid}_{R}M < \infty\).

First consider the case where \(M\) is Gorenstein injective, that is, \(\text{Gid}_{R}M = 0\). By definition, \(M\) is a kernel in a complete injective resolution. This means that there exists an exact sequence \(E = \cdots \rightarrow E_{1} \rightarrow E_{0} \rightarrow E_{-1} \rightarrow \cdots\) of injective \(R\)-modules, such that \(\text{Hom}_{R}(I, E)\) is exact for every injective \(R\)-module \(I\), and such that \(M \cong \ker(E_{1} \rightarrow E_{0})\). In particular, there exists a short exact sequence \(0 \rightarrow M' \rightarrow E \rightarrow M \rightarrow 0\), where \(E\) is injective, and \(M'\) is Gorenstein injective. Since \(M'\) is Gorenstein injective and \(\text{pd}_{R}M < \infty\), it follows by [4, Lemma 1.3] that \(\text{Ext}_{R}^{1}(M, M') = 0\). Thus \(0 \rightarrow M' \rightarrow E \rightarrow M \rightarrow 0\) is split-exact; so \(M\) is a direct summand of the injective module \(E\). Therefore, \(M\) itself is injective.

Next consider the case where \(\text{Gid}_{R}M > 0\). By [10, Theorem (2.15)] there exists an exact sequence \(0 \rightarrow M \rightarrow H \rightarrow C \rightarrow 0\) where \(H\) is Gorenstein injective and \(\text{id}_{R}C = \text{Gid}_{R}M - 1\). As in the previous case, since \(H\) is Gorenstein injective, there exists a short exact sequence \(0 \rightarrow H' \rightarrow I \rightarrow H \rightarrow 0\) where \(I\) is injective and \(H'\) is Gorenstein injective. Now consider the pull-back diagram with exact rows and
columns:

\[
\begin{array}{ccc}
0 & 0 & \downarrow M \\
\downarrow 0 & \downarrow H & \downarrow C \\
0 & \downarrow P & \downarrow I \\
\downarrow H' & \downarrow H' & 0
\end{array}
\]

Since \(I\) is injective and \(\text{id}_R M\) is finite, \(R\) is Gorenstein injective and \(\text{pd}_R M < 1\), it follows (as before) by Lemma 1.3] that \(\text{Ext}_R^1(M, H') = 0\). Consequently, the first column \(0 \to H' \to P \to M \to 0\) splits. Therefore \(P \cong M \oplus H'\), and hence \(\text{id}_R M \leq \text{id}_R P \leq \text{Gid}_R M\).

Theorem above has, of course, a dual counterpart:

**Theorem 2.2.** If \(M\) is an \(R\)-module with \(\text{id}_R M < 1\), then \(\text{Gpd}_R M = \text{pd}_R M\).

Theorem (2.6) below is a “flat version” of the two previous theorems. First recall the following.

**Definition 2.3.** The left finitistic projective dimension \(\text{LeftFPD}(R)\) of \(R\) is defined as

\[
\text{LeftFPD}(R) = \sup \{ \text{pd}_R M \mid M \text{ is a left } R\text{-module with } \text{pd}_R M < 1 \}.
\]

The right finitistic projective dimension \(\text{RightFPD}(R)\) of \(R\) is defined similarly.

**Remark 2.4.** When \(R\) is commutative and Noetherian, we have that \(\text{LeftFPD}(R)\) and \(\text{RightFPD}(R)\) equals the Krull dimension of \(R\), by Théorème (3.2.6) (Seconde partie)).

Furthermore, we will need the following result from Proposition (3.11):

**Proposition 2.5.** For any (left) \(R\)-module \(M\) the inequality

\[
\text{Gid}_R \text{Hom}_Z(M, \mathbb{Q}/\mathbb{Z}) \leq \text{Gfd}_R M
\]

holds. If \(R\) is right coherent, then we have \(\text{Gid}_R \text{Hom}_Z(M, \mathbb{Q}/\mathbb{Z}) = \text{Gfd}_R M\).

We are now ready to state:

**Theorem 2.6.** For any \(R\)-module \(M\), the following conclusions hold:

(i) Assume that \(\text{LeftFPD}(R)\) is finite. If \(\text{fd}_R M < \infty\), then \(\text{Gid}_R M = \text{id}_R M\).

(ii) Assume that \(R\) is left and right coherent with finite \(\text{RightFPD}(R)\). If \(\text{id}_R M < \infty\), then \(\text{Gfd}_R M = \text{fd}_R M\).

**Proof.** (i) If \(\text{fd}_R M < \infty\), then also \(\text{pd}_R M < \infty\), by Proposition 6] (since \(\text{LeftFPD}(R) < \infty\)). Hence the desired conclusion follows from Theorem (2.1) above.

(ii) Since \(R\) is left coherent, we have that \(\text{fd}_R \text{Hom}_Z(M, \mathbb{Q}/\mathbb{Z}) \leq \text{id}_R M < \infty\), by Lemma 3.1A]. By assumption, \(\text{RightFPD}(R) < \infty\), and therefore also
pd_{R,Hom_{\mathbb{Z}}(M,\mathbb{Q}/\mathbb{Z}) < \infty}, by [11 Proposition 6]. Now Theorem 2.4 gives that Gid_{R,Hom_{\mathbb{Z}}(M,\mathbb{Q}/\mathbb{Z}) = \text{id}_{R,Hom_{\mathbb{Z}}(M,\mathbb{Q}/\mathbb{Z})}

(without assumptions on \( R \)), and by Proposition 2.5 above, we also get Gfd_{R,M} = Gid_{R,Hom_{\mathbb{Z}}(M,\mathbb{Q}/\mathbb{Z})}, since \( R \) is right coherent. The proof is done. \( \square \)

3. A theorem on Gorenstein rings by Foxby

We end this paper by generalizing a theorem [8, Proposition 2.10] on Gorenstein rings by Foxby from 1979. For completeness, we briefly recall:

3.1. The small support. Assume that \( R \) is commutative and Noetherian. For an \( R \)-module \( M \), an integer \( n \), and a prime ideal \( p \) in \( R \), we write \( \beta^n_R(p,M) \), respectively, \( \mu^n_R(p,M) \), for the \( n \)th Betti number, respectively, \( n \)th Bass number, of \( M \) at \( p \).

Foxby [8, Definition p. 157] or [7, (14.8)] defines the small (or homological) support of an \( R \)-module \( M \) to be the set

\[
\text{supp}_R M = \{ p \in \text{Spec } R \mid \exists n \in \mathbb{N}_0: \beta^n_R(p,M) \neq 0 \}.
\]

Let us mention the most basic results about the small support, all of which can be found in [8] pp. 157–159 and [7] Chapter 14:

(a) The small support, \( \text{supp}_R M \), is contained in the usual (large) support, \( \text{Supp}_R M \), and \( \text{supp}_R M = \text{Supp}_R M \) if \( M \) is finitely generated. Also, if \( M \neq 0 \), then \( \text{supp}_R M \neq 0 \).

(b) \( \text{supp}_R M = \{ p \in \text{Spec } R \mid \exists n \in \mathbb{N}_0: \mu^n_R(p,M) \neq 0 \} \).

(c) Assume that \((R, m, k)\) is local. If \( M \) is an \( R \)-module with finite depth, that is, \( \text{depth}_R M := \inf \{ m \in \mathbb{N}_0 \mid \text{Ext}^m_R(k,M) \neq 0 \} < \infty \) (this happens for example if \( M \neq 0 \) is finitely generated), then \( m \in \text{supp}_R M \), by (b) above.

Now, given these facts about the small support, and the results in the previous section, the following generalization of [8] Proposition 2.10 is immediate:

**Theorem 3.2.** Assume that \( R \) is commutative and Noetherian. Let \( M \) be any \( R \)-module, and assume that any of the following four conditions is satisfied:

(i) \( \text{Gpd}_R M < \infty \) and \( \text{id}_R M < \infty \),

(ii) \( \text{pd}_R M < \infty \) and \( \text{Gid}_R M < \infty \),

(iii) \( R \) has finite Krull dimension, and \( \text{Gfd}_R M < \infty \) and \( \text{id}_R M < \infty \),

(iv) \( R \) has finite Krull dimension, and \( \text{fd}_R M < \infty \) and \( \text{Gid}_R M < \infty \).

Then \( R_p \) is a Gorenstein local ring for all \( p \in \text{supp}_R M \). \( \square \)

**Corollary 3.3.** Assume that \((R, m, k)\) is a commutative local Noetherian ring. If there exists an \( R \)-module \( M \) of finite depth, that is,

\[
\text{depth}_R M := \inf \{ m \in \mathbb{N}_0 \mid \text{Ext}^m_R(k,M) \neq 0 \} < \infty,
\]

and which satisfies either

(i) \( \text{Gfd}_R M < \infty \) and \( \text{id}_R M < \infty \), or

(ii) \( \text{fd}_R M < \infty \) and \( \text{Gid}_R M < \infty \),

then \( R \) is Gorenstein. \( \square \)
Acknowledgments

I would like to express my gratitude to my Ph.D. advisor Hans-Bjørn Foxby for his support, and our helpful discussions.
