RINGS WITH FINITE GORENSTEIN INJECTIVE DIMENSION

HENRIK HOLM

(Communicated by Bernd Ulrich)

Abstract. In this paper we prove that for any associative ring \( R \), and for any left \( R \)-module \( M \) with finite projective dimension, the Gorenstein injective dimension \( \text{Gid}_R M \) equals the usual injective dimension \( \text{id}_R M \). In particular, if \( \text{Gid}_R R \) is finite, then also \( \text{id}_R R \) is finite, and thus \( R \) is Gorenstein (provided that \( R \) is commutative and Noetherian).

1. Introduction

It is well known that among the commutative local Noetherian rings \((R, \mathfrak{m}, k)\), the Gorenstein rings are characterized by the condition \( \text{id}_R R < \infty \). From the dual of \([10] \) Proposition (2.27) \((6 \) Proposition 10.2.3) it follows that the Gorenstein injective dimension \( \text{Gid}_R (\cdot) \) is a refinement of the usual injective dimension \( \text{id}_R (\cdot) \) in the following sense:

For any \( R \)-module \( M \) there is an inequality \( \text{Gid}_R M \leq \text{id}_R M \), and if \( \text{id}_R M < \infty \), then there is an equality \( \text{Gid}_R M = \text{id}_R M \).

Now, since the injective dimension \( \text{id}_R R \) of \( R \) measures Gorensteinness, it is only natural to ask what does the Gorenstein injective dimension \( \text{Gid}_R R \) of \( R \) measure? As a consequence of Theorem (2.1) below, it turns out that:

An associative ring \( R \) with \( \text{Gid}_R R < \infty \) also has \( \text{id}_R R < \infty \) (and hence \( R \) is Gorenstein, provided that \( R \) is commutative and Noetherian).

This result is proved by Christensen \([2] \) Theorem (6.3.2) in the case where \((R, \mathfrak{m}, k)\) is a commutative local Noetherian Cohen-Macaulay ring with a dualizing module. The aim of this paper is to prove Theorem (2.1), together with a series of related results. Among these results is Theorem (3.2), which has the nice, and easily stated, Corollary (3.3):

Assume that \((R, \mathfrak{m}, k)\) is a commutative local Noetherian ring, and let \( M \) be an \( R \)-module of finite depth, that is, \( \text{Ext}^m_R (k, M) \neq 0 \) for some \( m \in \mathbb{N}_0 \) (this happens for example if \( M \neq 0 \) is finitely generated). If either

(i) \( \text{Gid}_R M < \infty \) and \( \text{id}_R M < \infty \) or

(ii) \( \text{fd}_R M < \infty \) and \( \text{Gid}_R M < \infty \),
then \( R \) is Gorenstein.

Key words and phrases. Gorenstein dimensions, homological dimensions, Gorenstein rings.
This corollary is also proved by Christensen \cite{2} Theorem (6.3.2)] in the case where \((R, \mathfrak{m}, k)\) is Cohen-Macaulay with a dualizing module. However, Theorem [3.2\] itself (dealing not only with local rings) is a generalization of \cite{8} Proposition 2.10] (in the module case) by Foxby from 1979.

We should briefly mention the history of Gorenstein injective, projective and flat modules: Gorenstein injective modules over an arbitrary associative ring, and the related Gorenstein injective dimension, was introduced and studied by Enochs and Jenda in \cite{3}. The dual concept, Gorenstein projective modules, was already introduced by Auslander and Bridger \cite{1} in 1969, but only for finitely generated modules over a two-sided Noetherian ring. Gorenstein flat modules were also introduced by Enochs and Jenda; please see \cite{5}.

1.1. Setup and notation. Let \(R\) be any associative ring with a nonzero multiplicative identity. All modules are—if not specified otherwise—left \(R\)-modules. If \(M\) is any \(R\)-module, we use \(\text{pd}_R M\), \(\text{id}_R M\), and \(\text{id}_R M\) to denote the usual projective, flat, and injective dimension of \(M\), respectively. Furthermore, we write \(\text{Gpd}_R M\), \(\text{Gid}_R M\), and \(\text{Gid}_R M\) for the Gorenstein projective, Gorenstein flat, and Gorenstein injective dimension of \(M\), respectively.

2. Rings with finite Gorenstein injective dimension

**Theorem 2.1.** If \(M\) is an \(R\)-module with \(\text{pd}_R M < \infty\), then \(\text{Gid}_R M = \text{id}_R M\). In particular, if \(\text{Gid}_R R < \infty\), then also \(\text{id}_R R < \infty\) (and hence \(R\) is Gorenstein, provided that \(R\) is commutative and Noetherian).

**Proof.** Since \(\text{Gid}_R M \leq \text{id}_R M\) always, it suffices to prove that \(\text{id}_R M \leq \text{Gid}_R M\). Naturally, we may assume that \(\text{Gid}_R M < \infty\).

First consider the case where \(M\) is Gorenstein injective, that is, \(\text{Gid}_R M = 0\). By definition, \(M\) is a kernel in a complete injective resolution. This means that there exists an exact sequence \(E = \cdots \rightarrow E_1 \rightarrow E_0 \rightarrow E_{-1} \rightarrow \cdots\) of injective \(R\)-modules, such that \(\text{Hom}_R(I, E)\) is exact for every injective \(R\)-module \(I\), and such that \(M \cong \ker(E_1 \rightarrow E_0)\). In particular, there exists a short exact sequence \(0 \rightarrow M' \rightarrow E \rightarrow M \rightarrow 0\), where \(E\) is injective, and \(M'\) is Gorenstein injective. Since \(M'\) is Gorenstein injective and \(\text{pd}_R M < \infty\), it follows by \cite{4} Lemma 1.3] that \(\text{Ext}^1_R(M, M') = 0\). Thus \(0 \rightarrow M' \rightarrow E \rightarrow M \rightarrow 0\) is split-exact; so \(M\) is a direct summand of the injective module \(E\). Therefore, \(M\) itself is injective.

Next consider the case where \(\text{Gid}_R M > 0\). By \cite{10} Theorem (2.15)] there exists an exact sequence \(0 \rightarrow M \rightarrow H \rightarrow C \rightarrow 0\) where \(H\) is Gorenstein injective and \(\text{id}_R C = \text{Gid}_R M - 1\). As in the previous case, since \(H\) is Gorenstein injective, there exists a short exact sequence \(0 \rightarrow H' \rightarrow I \rightarrow H \rightarrow 0\) where \(I\) is injective and \(H'\) is Gorenstein injective. Now consider the pull-back diagram with exact rows and
columns:

$$
\begin{array}{cccc}
0 & 0 & M & 0 \\
0 & P & I & 0 \\
H' & H' & 0 & 0 \\
0 & 0 & D & 0 \\
\end{array}
$$

Since $I$ is injective and id$_R P \leq$ Gid$_R M$ by the second row. Since $H'$ is Gorenstein injective and pd$_R M < \infty$, it follows (as before) by [4, Lemma 1.3] that Ext$_R^1(M, H') = 0$. Consequently, the first column $0 \rightarrow H' \rightarrow P \rightarrow M \rightarrow 0$ splits. Therefore $P \cong M \oplus H'$, and hence id$_R M \leq$ id$_R P \leq$ Gid$_R M$.

The theorem above has, of course, a dual counterpart:

**Theorem 2.2.** If $M$ is an $R$-module with id$_R M < \infty$, then Gpd$_R M =$ pd$_R M$.

Theorem (2.6) below is a \"flat version\" of the two previous theorems. First recall the following.

**Definition 2.3.** The left finitistic projective dimension LeftFPD($R$) of $R$ is defined as

$$\text{LeftFPD}(R) = \sup \{ \text{pd}_R M \mid \text{M is a left } R\text{-module with } \text{pd}_R M < \infty \}.$$ 

The right finitistic projective dimension RightFPD($R$) of $R$ is defined similarly.

**Remark 2.4.** When $R$ is commutative and Noetherian, we have that LeftFPD($R$) and RightFPD($R$) equals the Krull dimension of $R$, by [3, Théorème (3.2.6) (Seconde partie)].

Furthermore, we will need the following result from [10, Proposition (3.11)]:

**Proposition 2.5.** For any (left) $R$-module $M$ the inequality

$$\text{Gid}_R \text{Hom}_Z(M, \mathbb{Q}/\mathbb{Z}) \leq \text{Gfd}_R M$$

holds. If $R$ is right coherent, then we have Gid$_R \text{Hom}_Z(M, \mathbb{Q}/\mathbb{Z}) = \text{Gfd}_R M$.

We are now ready to state:

**Theorem 2.6.** For any $R$-module $M$, the following conclusions hold:

(i) Assume that LeftFPD($R$) is finite. If $\text{fd}_R M < \infty$, then Gid$_R M = \text{id}_R M$.

(ii) Assume that $R$ is left and right coherent with finite RightFPD($R$). If $\text{id}_R M < \infty$, then Gfd$_R M = \text{fd}_R M$.

**Proof.** (i) If $\text{fd}_R M < \infty$, then also $\text{pd}_R M < \infty$, by [11, Proposition 6] (since LeftFPD($R$) < $\infty$). Hence the desired conclusion follows from Theorem (2.1) above.

(ii) Since $R$ is left coherent, we have that $\text{fd}_R \text{Hom}_Z(M, \mathbb{Q}/\mathbb{Z}) \leq \text{id}_R M < \infty$, by [12, Lemma 3.1.4]. By assumption, RightFPD($R$) < $\infty$, and therefore also
pd_{R} \text{Hom}_{\mathbb{Z}}(M, \mathbb{Q}/\mathbb{Z}) < \infty$, by [11, Proposition 6]. Now Theorem 2.1 gives that 
Gid_{R} \text{Hom}_{\mathbb{Z}}(M, \mathbb{Q}/\mathbb{Z}) = \text{id}_{R} \text{Hom}_{\mathbb{Z}}(M, \mathbb{Q}/\mathbb{Z})$. It is well known that 
\text{fd}_{R} M = \text{id}_{R} \text{Hom}_{\mathbb{Z}}(M, \mathbb{Q}/\mathbb{Z})
(without assumptions on $R$), and by Proposition 2.5 above, we also get $G \text{fd}_{R} M = G \text{id}_{R} \text{Hom}_{\mathbb{Z}}(M, \mathbb{Q}/\mathbb{Z})$, since $R$ is right coherent. The proof is done.

3. A theorem on Gorenstein rings by Foxby

We end this paper by generalizing a theorem [8, Proposition 2.10] on Gorenstein rings by Foxby from 1979. For completeness, we briefly recall:

3.1. The small support. Assume that $R$ is commutative and Noetherian. For an $R$-module $M$, an integer $n$, and a prime ideal $p$ in $R$, we write $\beta_{n}^{R}(p, M)$, respectively, $\mu_{n}^{R}(p, M)$, for the $n$th Betti number, respectively, $n$th Bass number, of $M$ at $p$.

Foxby [8, Definition p. 157] or [7, (14.8)] defines the small (or homological) support of an $R$-module $M$ to be the set 
$$\text{supp}_{R} M = \{ p \in \text{Spec } R \mid \exists n \in \mathbb{N}_{0} : \beta_{n}^{R}(p, M) \neq 0 \}.$$ 

Let us mention the most basic results about the small support, all of which can be found in [8, pp. 157-159] and [7, Chapter 14]:

(a) The small support, $\text{supp}_{R} M$, is contained in the usual (large) support, $\text{Supp}_{R} M$, and $\text{supp}_{R} M = \text{Supp}_{R} M$ if $M$ is finitely generated. Also, if $M \neq 0$, then $\text{supp}_{R} M \neq 0$.

(b) $\text{supp}_{R} M = \{ p \in \text{Spec } R \mid \exists n \in \mathbb{N}_{0} : \mu_{n}^{R}(p, M) \neq 0 \}$.

(c) Assume that $(R, m, k)$ is local. If $M$ is an $R$-module with finite depth, that is,
$$\text{depth}_{R} M := \inf \{ m \in \mathbb{N}_{0} \mid \text{Ext}^{m}_{R}(k, M) \neq 0 \} < \infty$$
(this happens for example if $M \neq 0$ is finitely generated), then $m \in \text{supp}_{R} M$, by (b) above.

Now, given these facts about the small support, and the results in the previous section, the following generalization of [8, Proposition 2.10] is immediate:

**Theorem 3.2.** Assume that $R$ is commutative and Noetherian. Let $M$ be any $R$-module, and assume that any of the following four conditions is satisfied:

(i) $G \text{pd}_{R} M < \infty$ and $\text{id}_{R} M < \infty$,
(ii) $\text{pd}_{R} M < \infty$ and $G \text{id}_{R} M < \infty$,
(iii) $R$ has finite Krull dimension, and $G \text{fd}_{R} M < \infty$ and $\text{id}_{R} M < \infty$,
(iv) $R$ has finite Krull dimension, and $\text{fd}_{R} M < \infty$ and $G \text{id}_{R} M < \infty$.

Then $R_{p}$ is a Gorenstein local ring for all $p \in \text{supp}_{R} M$.

**Corollary 3.3.** Assume that $(R, m, k)$ is a commutative local Noetherian ring. If there exists an $R$-module $M$ of finite depth, that is,
$$\text{depth}_{R} M := \inf \{ m \in \mathbb{N}_{0} \mid \text{Ext}^{m}_{R}(k, M) \neq 0 \} < \infty,$$
and which satisfies either

(i) $G \text{fd}_{R} M < \infty$ and $\text{id}_{R} M < \infty$, or
(ii) $\text{fd}_{R} M < \infty$ and $G \text{id}_{R} M < \infty$.

then $R$ is Gorenstein.
Acknowledgments

I would like to express my gratitude to my Ph.D. advisor Hans-Bjørn Foxby for his support, and our helpful discussions.
