Objectives

The aim was to describe the potential of the SEIQoL-DW method and differences between the SEIQoL-DW method and the traditional OHIP questionnaire in generating usable information for decision making in oral rehabilitation.

Materials and methods

Fifty-seven patients were included in the study. The participants should be in need for an extensive oral rehabilitation and should have undergone a traditional examination/interview. The number of teeth, number of occluding teeth, region of missing teeth and removable dental prosthesis (RDP), if any, were recorded. The SEIQoL-DW included 4 steps: (1) Generation of cues by interview and selection of the five most important cues (2) Evaluation of the status of the five chosen cues on Visual Analogue Scale (3) Evaluation of the relative importance of the five cues using the DW-instrument (Fig. 1) (4) Calculation of a score for each cue and an overall SEIQoL-DW score for each patient For each participant, cues regarding reason for demanding treatment, symptoms, wishes and expectations from the traditional history taking were recorded. The OHIP (15) consisted of 49 questions. The patient answered how often a problem had occurred during the past month. A score from 0 to 4 was given to each answer depending on the level of occurrence. An overall OHIP score were summarized (9 and 96).}

Cues extracted from the OHIP, to be used in the analysis, were chosen to be the cues from the questions with answers of a score 2-4.

The participants of the study included respondents with varying degrees of oral function and could benefit from the results of the SEIQoL-DW method.

Results

Significantly more cues were generated by the SEIQoL-DW when compared to the traditional history taking. Significantly more cues were missing in both the traditional history taking and the OHIP when compared to the SEIQoL-DW (Table 1). The SEIQoL-DW generated additional types of cues when compared to both the traditional history taking and the OHIP (Table 2).

The number of teeth, tooth contacts, missing anterior teeth and RDPs showed no significant relationship to the number of cues generated by the SEIQoL-DW.

The overall SEIQoL-DW score was significantly related to the overall-OHIP score (Fig.2).

The participants opinion is shown in Table 3. Seventy to ninety percent was positive towards the use of the SEIQoL-DW in treatment planning.

Conclusions

The SEIQoL-DW method showed a potential for generating useful information in the oral rehabilitation decision making process. The method resulted in more cues and additional information compared to the traditional history taking and the OHIP questionnaire.

The status of the teeth did not influence the volume of information generated by the SEIQoL-DW.

A high percentage of the participants were positive towards the use of the SEIQoL-DW method.
